Description**Background of the Invention**

5 [0001] Percutaneous transluminal coronary angioplasty (PTCA) is widely used as the primary treatment modality in many patients with coronary artery disease. PTCA can relieve myocardial ischemia in patients with coronary artery disease by reducing lumen obstruction and improving coronary flow. The use of this surgical procedure has grown rapidly, with 39,000 procedures performed in 1983, nearly 150,000 in 1987, 200,000 in 1988, 250,000 in 1989, and over 500,000 PTCA's per year are estimated by 1994 (Popma et al., Amer. J. Med., 88: 16N-24N (1990); Fanelli et al, 10 Amer. Heart Jour., 119: 357-368 (1990); Johnson et al., Circulation, 78 (Suppl. II): II-82 (1988)). Stenosis following PTCA remains a significant problem, with from 25% to 35% of the patients developing restenosis within 1 to 3 months. Restenosis results in significant morbidity and mortality and frequently necessitates further interventions such as repeat angioplasty or coronary bypass surgery. As of 1993, no surgical intervention or post-surgical treatment has proven effective in preventing restenosis.

15 [0002] The processes responsible for stenosis after PTCA are not completely understood but may result from a complex interplay among several different biologic agents and pathways. Viewed in histological sections, restenotic lesions may have an overgrowth of smooth muscle cells in the intimal layers of the vessel (Johnson et al., Circulation, 78 (Suppl. II): II-82 (1988)). Several possible mechanisms for smooth muscle cell proliferation after PTCA have been suggested (Popma et al., Amer. J. Med., 88: 16N-24N (1990); Fanelli et al, Amer. Heart Jour., 119: 357-368 (1990); 20 Liu et al., Circulation, 79: 1374-1387 (1989); Clowes et al., Circ. Res., 56: 139-145 (1985)).

[0003] Compounds that reportedly suppress smooth muscle proliferation *in vitro* (Liu et al., Circulation, 79: 1374-1387 (1989); Goldman et al., Atherosclerosis, 65: 215-225 (1987); Wolinsky et al., JACC, 15 (2): 475-481 (1990)) may have undesirable pharmacological side effects when used *in vivo*. Heparin is an example of one such compound, which reportedly inhibits smooth muscle cell proliferation *in vitro* but when used *in vivo* has the potential adverse side effect 25 of inhibiting coagulation. Heparin peptides, while having reduced anti-coagulant activity, have the undesirable pharmacological property of having a short pharmacological half-life. Attempts have been made to solve such problems by using a double balloon catheter, i.e., for regional delivery of the therapeutic agent at the angioplasty site (e.g., Nabel et al., Science, 244: 1342-1344 (1989); U.S. Patent No. 4,824,436), and by using biodegradable materials impregnated with a drug, i.e., to compensate for problems of short half-life (e.g., Middlebrook et al., Biochem. Pharm., 38 (18): 30 3101-3110 (1989); U.S. Patent No. 4,929,602).

[0004] At least five considerations would, on their face, appear to preclude use of inhibitory drugs to prevent stenosis resulting from overgrowth of smooth muscle cells. First, inhibitory agents may have systemic toxicity that could create an unacceptable level of risk for patients with cardiovascular disease. Second, inhibitory agents might interfere with vascular wound healing following surgery and that could either delay healing or weaken the structure or elasticity of 35 the newly healed vessel wall. Third, inhibitory agents which kill smooth muscle cells could damage surrounding endothelium and/or other medial smooth muscle cells. Dead and dying cells also release mitogenic agents that might stimulate additional smooth muscle cell proliferation and exacerbate stenosis. Fourth, delivery of therapeutically effective levels of an inhibitory agent may be problematic from several standpoints: namely, a) delivery of a large number of molecules into the intercellular spaces between smooth muscle cells may be necessary, i.e., to establish favorable conditions for allowing a therapeutically effective dose of molecules to cross the cell membrane; b) directing an inhibitory drug into the proper intracellular compartment, i.e., where its action is exerted, may be difficult to control; and, c) 40 optimizing the association of the inhibitory drug with its intracellular target, e.g. a ribosome, while minimizing intercellular redistribution of the drug, e.g. to neighboring cells, may be difficult. Fifth, because smooth muscle cell proliferation takes place over several weeks it would appear *a priori* that the inhibitory drugs should also be administered over several weeks, perhaps continuously, to produce a beneficial effect.

[0005] As is apparent from the foregoing, many problems remain to be solved in the use of inhibitory drugs to effectively treat smooth muscle cell proliferation. Thus, there is a need for a method to inhibit or reduce stenosis due to proliferation of vascular smooth muscle cells following traumatic injury to vessels such as occurs during vascular surgery. There is also a need to deliver compounds to vascular smooth muscle cells which exert inhibitory effects over 50 extended periods of time.

Summary of the Invention

55 [0006] The present invention provides the use of cytoskeletal inhibitors in the preparation of medicaments to inhibit or reduce diminution in the vessel lumen area of a mammalian vessel, e.g. for administration to a procedurally traumatized, e.g., by an angioplasty procedure, mammalian vessel. Preferred cytoskeletal inhibitor in the practice of the present invention, include, for example, taxol and analogs or derivatives thereof such as taxotere, or a cytochalasin, such as cytochalasin B, cytochalasin C, cytochalasin D, or analogs or derivatives thereof. The administration of such

cytoskeletal inhibitors is effective to biologically stent the vessel, inhibit or reduce vascular remodeling of the vessel, inhibit or reduce vascular smooth muscle cell proliferation, or any combination thereof. The administration of the cytoskeletal inhibitors preferably is carried out during the procedure which traumatizes the vessel, e.g., during the angioplasty or other vascular surgical procedure. The invention also provides pharmaceutical compositions and dosage forms containing cytoskeletal inhibitors for use in the present method, as well as kits containing them.

[0007] Thus, medicaments, pharmaceutical compositions and dosage forms described herein may be used to biologically stent a traumatized mammalian blood vessel. As used herein, "biological stenting" means the fixation of the vascular lumen in a dilated state near its maximal systolic diameter. The method of biologically stenting a vessel comprises the administration of an effective amount of a cytoskeletal inhibitor to the blood vessel. Preferably, the cytoskeletal inhibitor is dispersed in a pharmaceutically acceptable liquid carrier, e.g., about 0.1 to about 10 μ g for cytochalasin B/ml of vehicle, and preferably administered locally via a catheter. Preferably, a portion of the amount administered penetrates to at least about 6 to 9 cell layers of the inner tunica media of the vessel and so is effective to biologically stent the vessel. Preferred embodiments of the invention contain a cytochalasin or an analog thereof dispersed in a pharmaceutically acceptable liquid carrier at about 0.001 to about 25 μ g per ml of aqueous vehicle.

[0008] Preferred catheter administration conditions include employing a catheter to deliver about 4 to about 25 ml of a composition comprising the cytoskeletal inhibitor dispersed or dissolved in a pharmaceutically acceptable liquid vehicle. The cytoskeletal inhibitor is delivered at a hub pressure of about 3 to about 8 atm, more preferably about 4 to about 5 atm, for about 0.5 to about 5 minutes, more preferably for about 0.7 to about 3 minutes. Preferred hydrostatic head pressures for catheter administration include about 0.3 to about 1.0 atm, more preferably about 0.5 to about 0.75 atm. The amount of cytoskeletal inhibitor is controlled so as to allow vascular smooth muscle cells to continue to synthesize protein, which is required to repair minor cell trauma, and to secrete interstitial matrix, thereby facilitating the fixation of the vascular lumen in a dilated state near its maximal systolic diameter, i.e., to provide a biological stent of the vessel. Preferably, the cytoskeletal inhibitor is administered directly or substantially directly to the traumatized area of the vascular smooth muscle tissue.

[0009] The medicaments, pharmaceutical compositions and dosage forms may be used to inhibit or reduce vascular remodeling of a traumatized mammalian blood vessel, by administering an effective amount of the cytoskeletal inhibitor to the traumatized blood vessel.

[0010] As described hereinbelow, a dose response study showed that cytochalasin B had a two logarithmic therapeutic index (TI). A large therapeutic index allows the diffusion of therapeutic levels of the agent from the delivery system, e.g., an implantable device, without toxicity to cells immediately adjacent to the exit port of the system. Moreover, even at the maximum concentration of cytochalasin B in a liquid vehicle, there was little or no toxicity observed in cells adjacent to the delivery system. It was also found that cytochalasin B and taxol both inhibit intimal proliferation in vessels subjected to a procedural vascular trauma. This inhibition results in a more rapid and complete endothelialization of the vessel wall following the trauma.

[0011] In particular, the medicaments, compositions and dosage forms may be used to inhibit or reduce diminution in vessel lumen volume in a procedurally traumatized mammalian blood vessel. In such methods an effective amount of cytoskeletal inhibitor is administered to the blood vessel of a mammal, wherein the cytoskeletal inhibitor is in substantially pure substantially crystalline form and wherein the crystals are of a size which results in sustained release of the cytoskeletal inhibitor. Preferably, the crystals are of a size of about 0.1 micron to about 10 mm, preferably about 1 micron to about 25 micron, in size. Methods to determine the size of crystals useful for sustained release are well known to the art. Preferably, the cytoskeletal inhibitor is administered in situ, by means of an implantable device, wherein the cytoskeletal inhibitor is releasably embedded in, coated on, or embedded in and coated on, the implantable device. Preferably, the crystalline cytoskeletal inhibitor is releasably embedded in, or dispersed in, an adventitial wrap, e.g., a silicone membrane. For example, a preferred therapeutic implantable device of the invention comprises about 5 to about 70, preferably about 7 to about 50, and more preferably about 10 to about 30, weight percent of a cytochalasin, e.g., cytochalasin B or an analog thereof, per weight percent of the adventitial wrap. Another preferred therapeutic implantable device of the invention comprises about 1 to about 70, preferably about 2 to about 50, and more preferably about 3 to about 10, weight percent of taxol or an analog thereof per weight percent of the adventitial wrap. Alternatively, a preferred therapeutic implantable device of the invention comprises about 30 to about 70, preferably about 30 to about 60, and more preferably about 30 to about 50, weight percent of taxol or an analog thereof per weight percent of the adventitial wrap. Alternatively, the crystalline cytoskeletal inhibitor may be suspended in a vehicle which yields a solution comprising the crystals, i.e., it is a saturated solution.

[0012] Thus in a first aspect the present invention provides the use of a dosage form comprising a cytoskeletal inhibitor, wherein the cytoskeletal inhibitor is in substantially crystalline form and wherein the crystals are of a size which results in sustained release of the cytoskeletal inhibitor, for the preparation of a medicament to inhibit or reduce diminution in vessel lumen area of a procedurally traumatized mammalian blood vessel, wherein said dosage form is administered to the mammalian blood vessel.

[0013] In a second aspect, the present invention provides the use of a dosage form comprising a cytochalasin or an

analog thereof in solid form in a non-liquid matrix for the preparation of a medicament to inhibit or reduce diminution in vessel lumen area of a mammalian blood vessel wherein said dosage form is administered to the mammalian blood vessel wherein the non-liquid matrix is a gel, paste or membrane.

[0014] The crystals may be administered to the blood vessel as an emulsion or microemulsion. The amount of the cytoskeletal inhibitor is effective to inhibit or reduce diminution in vessel lumen area of the mammalian blood vessel. Preferably, the emulsion or micro emulsion is in sustained release dosage form. Preferably, the microemulsion is about 5 nm to about 1000 nm, and more preferably about 30 nm to about 300 nm, in diameter.

[0015] The crystals may comprise microparticles or nanoparticles comprising the cytoskeletal inhibitor, e.g., cytochalasin, taxol, or analogs thereof. The sustained release dosage form is administered via an implantable device which is not a catheter, preferably not a catheter used to perform bloodless angioplasty. The amount administered is effective to inhibit or reduce diminution in vessel lumen area of the mammalian blood vessel. The sustained release dosage form preferably comprises microparticles of 4 to about 50 microns in diameter. The sustained release dosage form can also preferably comprise about 2 to about 50, and more preferably greater than 3 and less than 10, microns in diameter. For nanoparticles, preferred sizes include about 10 to about 5000, more preferably about 20 to about 500, and more preferably about 50 to about 200, nanometers.

[0016] Thus, the invention provides a medicament for administering to a procedurally traumatized mammalian blood vessel containing a substantially pure substantially solid form of a cytochalasin or an analog thereof effective to inhibit or reduce diminution in vessel lumen area of the mammalian blood vessel. Preferred solid forms include, but are not limited to, microparticles or nanoparticles comprising the cytochalasin or analog thereof, crystals or microcrystals of the cytochalasin or analog thereof, microparticles or nanoparticles comprising crystals or microcrystals of the cytochalasin or analog thereof, or a gel or paste comprising the cytochalasin or analog thereof.

[0017] Also provided is a kit comprising, separately packaged, at least one implantable device adapted for the in situ delivery, preferably local delivery, of at least one cytoskeletal inhibitor to a site in the lumen of a traumatized mammalian vessel and at least one unit dosage form of the cytoskeletal inhibitor as described hereinbefore adapted for delivery by said device. The delivery of the unit dosage form to the traumatized vessel via the device is effective to biologically stent the vessel, inhibit or reduce the vascular remodeling of the vessel, inhibit or reduce vascular smooth muscle cell proliferation, or any combination thereof.

[0018] The unit dosage-form may comprise the crystalline cytoskeletal inhibitor in an emulsion or microemulsion comprising at least one cytoskeletal inhibitor. The delivery of the unit dosage form via the device to the traumatized mammalian vessel is effective to inhibit or reduce diminution in vessel lumen diameter in the vessel.

[0019] The unit dosage form may alternatively comprise the crystalline cytoskeletal inhibitor in microparticles or nanoparticles e.g. comprising taxol or an analog thereof. Preferably, the kit also comprises a second unit dosage form comprising a pharmaceutically acceptable liquid carrier vehicle for dispersing said microparticles or said nanoparticles prior to delivery. The delivery of the dispersed microparticles or nanoparticles to the traumatized mammalian vessel is effective to inhibit or reduce diminution in vessel lumen diameter in the vessel.

[0020] Yet another embodiment of the invention is a pharmaceutical composition suitable for administration by means of an implantable device. The composition comprises an amount of a cytochalasin or an analog thereof (preferably substantially pure) in solid form, preferably crystalline, effective to inhibit or reduce stenosis or restenosis of a mammalian vessel traumatized by a surgical procedure; and a pharmaceutically acceptable non-liquid release matrix for said cytochalasin or analog thereof, wherein the non-liquid release matrix is a gel, paste or membrane, e.g., a silicone membrane, and the device is a shunt or an adventitial wrap.

[0021] The invention also provides a pharmaceutical composition comprising an amount of a substantially pure solid cytochalasin or analog thereof effective to inhibit or reduce stenosis or restenosis of a mammalian vessel traumatized by a surgical procedure, wherein said cytochalasin or analog thereof is in crystalline form.

[0022] The crystalline cytochalasin in said composition may be in an emulsion or microemulsion.

[0023] The invention also provides therapeutic devices. One embodiment of the invention comprises a therapeutic shunt comprising an amount of a cytoskeletal inhibitor in solid form effective to inhibit stenosis or reduce restenosis following placement of the therapeutic shunt. Compositions or medicaments of the invention may be administered using a therapeutic artificial graft. Another embodiment of the invention comprises a therapeutic adventitial wrap comprising an amount of a cytoskeletal inhibitor in solid form effective to inhibit stenosis or reduce restenosis following placement of the wrap.

[0024] Also provided by the invention is a therapeutic device comprising a stent overlaid with an artificial graft, wherein the artificial graft comprises about 5 to 70 weight percent of a cytoskeletal inhibitor in solid form.

[0025] The medicaments, compositions, kits and devices described above may be used to inhibit diminution of vessel lumen diameter. The cytoskeletal inhibitor is preferably administered via an implantable device, wherein the implantable device is not a catheter which has a first and a second expansile member, i.e., balloons, which are disposed on opposite sides of the vessel area to be treated in order to isolate the portion of the vessel to be treated prior to cytoskeletal inhibitor administration. Preferably, the isolated portion of the vessel is not washed to remove blood prior to cytoskeletal

inhibitor administration ("bloodless angioplasty"). "Isolated," as used above, does not mean occlusive contact of the actual treatment area by the catheter balloon, which is preferred in the practice of the present invention. Moreover, bloodless angioplasty, such as that described in Slepian, U.S. Patent No. 5,328,471, i.e., in which the region to be treated is washed, may introduce trauma or further trauma to the vessel, may increase the potential for complications and is not necessary to achieve a beneficial effect.

[0026] As mentioned above, medicaments, compositions, kits and devices of the invention containing a dosage form of a cytochalasin or an analog thereof in a non-liquid vehicle or matrix effective inhibit or reduce diminution in vessel lumen area of a mammalian blood vessel may be administered to the vessel. The dosage form is a substantially solid dosage form. The non-liquid vehicle or matrix is a gel, paste, or a membrane, but does not include microparticles, nanoparticles, and the like, which comprises the cytochalasin or analog thereof.

[0027] As mentioned above, the invention also provides a kit comprising, preferably separately packaged, an implantable device adapted for the delivery of at least one cytoskeletal inhibitor to a site in the lumen of a traumatized mammalian vessel and a unit dosage form comprising at least one cytoskeletal inhibitor, wherein the administration of at least a portion of the unit dosage form is effective to inhibit or reduce diminution in vessel lumen diameter of the vessel. The device is not a catheter which has a first and a second expansile member which are disposed on opposite sides of the region to be treated so as to isolate a portion of the vessel to be treated prior to administration or wherein the isolated portion of the vessel is not washed to remove blood prior to administration.

[0028] As referred herein, the unit dosage form may comprise a vial comprising about 10 to about 30 ml of about 0.001 μ g to about 25 μ g of a cytoskeletal inhibitor, preferably a cytochalasin, per ml of liquid vehicle, wherein the unit dosage form is adapted for delivery via an implantable device, and wherein the vial is labeled for use in treating or inhibiting stenosis or restenosis. Preferably, the unit dosage form comprises a vial comprising about 10 to about 30 ml of about 0.01 μ g to about 10 μ g of cytochalasin B per ml of liquid vehicle. Thus, the volume present in a vial may be greater than, or about the same as, the volume present in the implantable device. Likewise, the volume present in the implantable device may be greater than, or about the same as, the volume administered. Similarly, the volume administered may be greater than, or about the same as, the volume which has a beneficial effect.

[0029] The unit dosage may comprise a vial comprising a cytostatic amount of a cytoskeletal inhibitor in a pharmaceutically acceptable liquid vehicle. Preferably, the cytoskeletal inhibitor comprises a cytochalasin, taxol, or an analog thereof.

[0030] Particularly preferred embodiments of the invention are described in the sub-claims.

Brief Description of the Drawings

[0031]

FIGURE 1A is a photomicrograph of vascular smooth muscle cells of a 24-year-old male patient.

FIGURE 1B is a photomicrograph of vascular smooth muscle cells in an artery of a 24-year-old male patient with vascular smooth muscle binding protein bound to the cell surface and membrane. The patient received the vascular smooth muscle binding protein by i.v. administration 4 days before the arterial tissue was prepared for histology. FIGURE 2 depicts a first scheme for chemical coupling of a therapeutic agent to a vascular smooth muscle binding protein.

FIGURE 3 depicts a second scheme for chemical coupling of a therapeutic agent to a vascular smooth muscle binding protein.

FIGURE 4A graphically depicts experimental data showing rapid binding of vascular smooth muscle binding protein to marker-positive test cells *in vitro*.

FIGURE 4B graphically depicts experimental data showing rapid binding of vascular smooth muscle binding protein to vascular smooth muscle cells *in vitro*.

FIGURE 5A presents graphically experimental data showing undesirable cytotoxicity of even low levels of therapeutic conjugate (i.e., RA-NR-AN-01), and the free RA therapeutic agent, when vascular smooth muscle cells were treated for 24 hours *in vitro*.

FIGURE 5B graphically presents experimental data showing the effects of RA-NR-AN-01 therapeutic conjugate on metabolic activity of marker-positive and -negative cells. The data show undesirable nonspecific cytotoxicity of the conjugate for all these cells in a 24 hour treatment *in vitro*. The non-specificity results from extracellular hydrolysis of the coupling ligand which exposes the tested cells to free drug.

FIGURE 6A graphically depicts experimental data showing undesirable nonspecific cytotoxicity of PE-NR-AN-01 therapeutic conjugate for marker-positive and marker-negative test cells after 24 hours of treatment *in vitro*, even though the 24 hour treatment was followed by an overnight recovery period prior to testing the metabolic activity. FIGURE 6B depicts experimental data showing nonspecific cytotoxicity of the free PE therapeutic agent on marker-positive and -negative test cells after 24 hours of treatment *in vitro*.

FIGURE 7A graphically presents experimental data showing that a short 5 minute "pulse" treatment, i.e., instead of 24 hours, followed by exposure to [3H]leucine, with free RA therapeutic agent being nonspecifically cytotoxic, i.e., for control HT29 marker-negative cells, but, in contrast, the RA-NR-AN-01 therapeutic conjugate is not cytotoxic in this "pulse" treatment.

FIGURE 7B presents graphically experimental data showing that free RA therapeutic agent is nonspecifically cytotoxic for control HT29 marker-negative cells, even in a 5' "pulse" treatment followed by a 24 hour recovery period prior to [3H]leucine exposure, but, in contrast, the RA-NR-AN-01 therapeutic conjugate is not cytotoxic to cells.

FIGURE 7C presents graphically results of experiments showing that "pulse" treatment of cells *in vitro* with the RA-NR-AN-01 therapeutic conjugate inhibits cellular activity in marker-positive A375 cells, as measured by protein synthesis.

FIGURE 7D presents graphically experimental data showing that "pulse" treatment of cells *in vitro* with the RA-NR-AN-01 therapeutic conjugate did not exert long-lasting inhibitory effects on cellular activity in marker-positive cells, since protein synthesis in 375 cells was not inhibited when the cells were allowed an overnight recovery period prior to testing *in vitro*.

FIGURE 8A presents graphically experimental data showing that while a "pulse" treatment of cells *in vitro* with free RA agent was nonspecifically cytotoxic, the RA-NR-AN-01 therapeutic conjugate did not exert long-lasting inhibitory effects on cellular activity in vascular smooth muscle cells, as evidenced by metabolic activity in BO54 cells that were allowed a 48 hour recovery period prior to testing.

FIGURE 8B graphically depicts experimental data similar to those presented in FIGURE 8A, above, but using a second marker-positive cell type, namely A375, the data show that "pulse" treatment with the RA-NR-AN-01 therapeutic conjugate did not exert long-lasting inhibitory effects on cellular activity, as measured by metabolic activity in A375 cells that were allowed a 48 hour recovery period prior to testing.

FIGURE 8C graphically depicts results similar to those presented in FIGURE 8A and FIGURE 8B, above, but using a marker-negative control cell type, namely HT29. The results show that the "pulse" treatment with the RA-NR-AN-01 therapeutic conjugate did not exert long-lasting inhibitory effects on the cellular activity of marker-negative control cells, as measured by metabolic activity in HT29 cells that were allowed a 48 hour recovery period prior to testing.

FIGURE 9A shows stenosis due to intimal smooth muscle cell proliferation in a histological section of an untreated artery 5 weeks after angioplasty in an animal model.

FIGURE 9B shows inhibition of stenosis in a histological section of an artery treated with therapeutic conjugate at 5 weeks after angioplasty in an animal model.

FIGURE 10A graphically depicts experimental data comparing protein synthesis and DNA synthesis inhibition capability of suramin with respect to vascular smooth muscle cells.

FIGURE 10B graphically depicts experimental data comparing protein synthesis and DNA synthesis inhibition capability of staurosporin with respect to vascular smooth muscle cells.

FIGURE 10C graphically depicts experimental data comparing protein synthesis and DNA synthesis inhibition capability of nitroglycerin with respect to vascular smooth muscle cells.

FIGURE 10D graphically depicts experimental data comparing protein synthesis and DNA synthesis inhibition capability of cytochalasin B with respect to vascular smooth muscle cells.

FIGURE 11 shows a tangential section parallel to the inner surface of a smooth muscle cell which is magnified 62,500 times and is characterized by numerous endocytic vesicles, several of which contain antibody coated gold beads in the process of being internalized by the cell *in vitro*.

FIGURE 12 shows a smooth muscle cell which is magnified 62,500 times and is characterized by a marked accumulation of gold beads in lysosomes at 24 hours following exposure of the cell to the beads *in vitro*.

FIGURE 13 shows a smooth muscle cell which is magnified 62,500 times and is characterized by accumulation of gold beads in lysosomes *in vivo*.

FIGURE 14 depicts an *in vivo* dose response study of the effects of cytochalasin B on the luminal area of pig femoral arteries.

FIGURE 15 is a graph depicting the inhibition of smooth muscle cell proliferation in traumatized vessels over time by cytochalasin B (CB) or taxol (TAX) administered in silicone wraps (SW).

FIGURE 16 is a graph depicting the inhibition of smooth muscle cell proliferation in traumatized vessels over time by 10% or 30% wt/wt CB in SW or 5% wt/wt TAX in SW.

FIGURE 17 is a graph depicting the inhibition of smooth muscle cell proliferation in traumatized vessels over time by CB or TAX in silicone, CB in a collagen gel supported by a bovine collagen mesh (CG-CM) or CB in a pluronic gel supported by a bovine collagen mesh (PG-CW).

Detailed Description of the Invention**Definitions**

[0032] "Therapeutic conjugate" means a vascular smooth muscle or an interstitial matrix binding protein coupled (e.g., optionally through a linker moiety) to a cytoskeletal inhibitor. Therapeutic conjugates used according to the invention as described herein are obtained by coupling a vascular smooth muscle binding protein to a cytoskeletal inhibitor. In the therapeutic conjugate, the vascular smooth muscle binding protein performs the function of targeting the therapeutic conjugate to vascular smooth muscle cells or pericytes, and the cytoskeletal inhibitor performs the function of inhibiting the cellular activity or proliferation of the smooth muscle cell or pericyte.

[0033] "Therapeutic agent" as referred to herein is a cytoskeletal inhibitor.

[0034] "Target" and "marker" are used interchangeably in describing the present conjugates to mean a molecule recognized in a specific manner by the matrix or vascular smooth muscle binding protein, e.g., an antigen, polypeptide antigen or cell surface carbohydrate (e.g., a glycolipid, glycoprotein; or proteoglycan) that is expressed on the cell surface membranes of a vascular smooth muscle cell or a matrix structure.

[0035] "Epitope" is used to refer to a specific site within the "target" molecule that is bound by the matrix or smooth muscle binding protein, e.g., a sequence of three or more amino acids or saccharides.

[0036] "Coupled" is used to mean covalent or non-covalent chemical association (i.e., hydrophobic association as through van der Waals forces or charge-charge interactions) of the matrix or vascular smooth muscle binding protein with the therapeutic agent, including by chelation. Preferably, the binding proteins are associated with the cytoskeletal inhibitors by means of covalent bonding.

[0037] "Linker" means a moiety that couples the matrix or smooth muscle binding protein to a cytoskeletal inhibitor, e.g., as derived from an organic chemical coupling agent.

[0038] As used herein, "substantially" pure means at least about 90%, preferably at least about 98%, and more preferably at least about 99%, free of contaminants when assayed by methods conventionally employed by the art.

[0039] As used herein, "substantially" solid or crystalline means at least about 90%, preferably at least about 98%, and more preferably at least about 99%, free of non-solid or non-crystalline forms or phases when assayed by methods conventionally employed by the art.

[0040] "Migration" of smooth muscle cells means movement of these cells *in vivo* from the medial layers of a vessel into the intima, which may also be studied *in vitro* by following the motion of a cell from one location to another (e.g., using time-lapse cinematography or a video recorder and manual counting of smooth muscle cell migration out of a defined area in the tissue culture over time).

[0041] "Proliferation" means an increase in cell number, i.e., by mitosis of the cells. As used herein "smooth muscle cells" does not refer to neoplastic vascular smooth muscle cells, i.e., cancer cells.

[0042] "Implantable device" means any material that is capable of retaining and releasing a cytoskeletal inhibitor so as to deliver it *in situ* in a controlled fashion to a mammalian vessel. An implantable device includes devices which are placed in the lumen of the vessel, e.g., an indwelling catheter or stent, or on the exterior of a vessel, e.g., an adventitial wrap, mesh or covering, or which become a part of the vessel itself, for example to replace a portion of a diseased or traumatized vessel, e.g., a synthetic graft. The implantable device may comprise the cytoskeletal inhibitor in a form which is releasably embedded in and/or coated on the device. The cytoskeletal inhibitor may also be releasably embedded in and/or coated on a pharmaceutically acceptable release carrier matrix, which may be applied to and/or embedded in the device or administered directly to a vessel. For example, a matrix useful in certain embodiments of the invention includes, but is not limited to, microparticles, nanoparticles, a gel, a paste, or a permeable membrane. An implantable device may be implanted for a limited amount of time, e.g., catheter or infusion needle delivery of a cytoskeletal inhibitor, or for a prolonged period of time, e.g., a stent or graft. Vessels, into which the implantable device of the invention may be inserted, include, but are not limited to, coronary, femoral, carotid and peripheral vessels.

[0043] "Abnormal or pathological or inappropriate" with respect to an activity or proliferation means division, growth or migration of cells, but not cancer cells, that occurs more rapidly or to a significantly greater extent than typically occurs in a normally functioning cell of the same type or in lesions not found in healthy tissue.

[0044] "Expressed" means mRNA transcription and translation with resultant synthesis, glycosylation, and/or secretion of a polypeptide by a cell, e.g., CSPG synthesized by a vascular smooth muscle cell or pericyte.

[0045] "Vascular remodeling" means a diminution in vessel lumen volume, diameter or area that is not the result of neointimal thickening or smooth muscle cell proliferation, and which generally occurs after a procedural vascular trauma. Thus, a reduction in the area ("constriction") circumscribed by the internal elastic lamina or membrane (IEL) without significant amounts of neointimal formation is termed "vascular remodeling." See Isner, *Circ.*, 89 2937 (1994). The luminal cross-sectional area of a vessel can be measured by direct planimetry, e.g., by intravascular ultrasound (IVUS) or at necropsy. As used herein, "vascular remodeling" does not include compensatory enlargement of a vessel which accompanies neointimal proliferation so as to accommodate the intimal increase. This compensatory enlarge-

ment has also been referred to as "positive" vascular remodeling.

[0046] "Sustained release" means a dosage form designed to release a cytoskeletal inhibitor therefrom for a time period from about 0.0005 to about 180, preferably from about 1-3 to about 150, and more preferably from about 30 to about 120, days. Release over a longer time period is also contemplated as "sustained release" in the context of the present invention. Moreover, it is contemplated that the methods described herein can be practiced with a locally or systemically administered sustained release dosage form.

[0047] "Dosage form" includes a formulation comprising a free (non-targeted or non-binding partner associated) cytoskeletal inhibitor, as well as a sustained release formulation comprising a cytoskeletal inhibitor. For example, sustained release formulations can comprise microparticles or nanoparticles, microemulsions, biodegradable or non-biodegradable polymeric materials, or any combination thereof, comprising a cytoskeletal inhibitor dispersed therein, as well as crystalline forms of the cytoskeletal inhibitor as described hereinbefore. A targeted or binding partner associated dosage form includes a sustained release therapeutic formulation comprising microparticles or nanoparticles, microemulsions, and/or biodegradable or non-biodegradable polymeric materials. The sustained release dosage form is linked to one or more binding proteins or peptides, so as to deliver a cytoskeletal inhibitor dispersed therein to a target cell population which binds to the binding protein or peptide.

[0048] "Cytochalasin" includes a fungal metabolite exhibiting an inhibitory effect on target cellular metabolism, including prevention of contraction or migration of vascular smooth muscle cells. Preferably, cytochalasins inhibit the polymerization of monomeric actin (G-actin) to polymeric form (F-actin), thereby inhibiting cell functions requiring cytoplasmic micro filaments. Cytochalasins typically are derived from phenylalanine (cytochalasins), tryptophan (chaetoglobosins), or leucine (aspochalasins), resulting in a benzyl, indol-3-yl methyl or isobutyl group, respectively, at position C-3 of a substituted perhydroisoindole-1-one moiety (Formula I or II).

[0049] The perhydroisoindole moiety in turn contains an 11-, 13- or 14-atom carbocyclic- or oxygen-containing ring linked to positions C-8 and C-9. All naturally occurring cytochalasins contain a methyl group at C-5; a methyl or methylene group at C-12; and a methyl group at C-14 or C-16. Exemplary cytochalasins include cytochalasin A, cytochalasin B, cytochalasin C, cytochalasin D, cytochalasin E, cytochalasin F, cytochalasin G, cytochalasin H, cytochalasin J, cytochalasin K, cytochalasin L, cytochalasin M, cytochalasin N, cytochalasin O, cytochalasin P, cytochalasin Q, cytochalasin R, cytochalasin S, chaetoglobosin A, chaetoglobosin B, chaetoglobosin C, chaetoglobosin D, chaetoglobosin E, chaetoglobosin F, chaetoglobosin G, chaetoglobosin J, chaetoglobosin K, deoxaphomin, proxiphomin, protophomin, zygosporin D, zygosporin E, zygosporin F, zygosporin G, aspochalasin B, aspochalasin C, aspochalasin D and the like, as well as functional equivalents and derivatives thereof. Certain cytochalasin derivatives are set forth in Japanese Patent Nos. 72 01,925; 72 14,219; 72 08,533; 72 23,394; 72 01924; and 72 04,164. Cytochalasin B is used in this description as a typical cytochalasin.

[0050] As referred to herein, "taxol" includes taxol as well as functional analogs, equivalents or derivatives thereof. For example, derivatives and analogs of taxol include, but are not limited to, taxotere, baccatin, 10-deacetyltaxol, 7-xylosyl-10-deacetyltaxol, cephalomannine, 10-deacetyl-7-epitaxol, 7 epitaxol, 10-deacetylbaccatin III, 10-deacetylcephalomannine and analogs or derivatives disclosed in Kingston et al. (*New Trends in Nat. Prod. Chem.*, **26**, 219 (1986)), Bringli et al. (WO 93/17121), Golik et al. (EPA 639577), Kelly et al. (WO 95/20582), and Cassady and Dourous (eds., In: *Anticancer Agents Based on Natural Product Models*, Academic Press, NY (1980)). Methods for preparing taxol and numerous analogs and derivatives thereof are well known to the art.

[0051] "Macrocyclic trichothecene" is intended to mean any one of the group of structurally related sesquiterpenoid macrocyclic mycotoxins produced by several species of fungi and characterized by the 12,13-epoxytrichothec-9-ene basic structure, e.g., verrucarins and roridins that are the products of secondary metabolism in the soil fungi *Myrothecium verrucaria* and *Myrothecium roridium*.

[0052] There are two broad classes of trichothecenes: those that have only a central sesquiterpenoid structure and those that have an additional macrocyclic ring (simple and macrocyclic trichothecenes, respectively). The simple trichothecenes may be subdivided into three groups (i.e., Group A, B, and C) as described in U.S. Patent Nos. 4,744,981 and 4,906,452 (incorporated herein by reference). Representative examples of Group A simple trichothecenes include: scirpene, roridin C, dihydrotrichothecene, scirpen-4, 8-diol, verrucarol, scirpentriol, T-2 tetraol, pentahydroxyscirpene, 4-deacetylneosolaniol, trichodermin, deacetylcalonecetrin, calonecetrin, diacetylverrucarol, 4-monoacetoxyscirpenol, 4,15-diacetoxyscirpenol, 7-hydroxydiacetoxyscirpenol, 8-hydroxydiacetoxyscirpenol (neosolaniol), 7,8-dihydroxydiacetoxyscirpenol, 7-hydroxy-8-acetyldiacetoxyscirpenol, 8-acetylneosolaniol, NT-1, NT-2, HT-2, T-2, and acetyl T-2 toxin. Representative examples of Group B simple trichothecenes include: trichothecolone, trichothecin, deoxynivalenol, 3-acetyldeoxynivalenol, 5-acetyldeoxynivalenol, 3,15-diacetyldeoxynivalenol, nivalenol, 4-acetylnivalenol (fusarenon-X), 4,15-idacetylnivalenol, 4,7,15-triacetylnivalenol, and tetra-acetylnivalenol. Representative examples of Group C simple trichothecenes include: crotochol and crotochin. Representative macrocyclic trichothecenes include verrucarin A, verrucarin B, verrucarin J (Satratoxin C), roridin A, roridin D, roridin E (satratoxin D), roridin H, satratoxin F, satratoxin G, satratoxin H, vertisporin, mytoxin A, mytoxin C, mytoxin B, myrotoxin A, myrotoxin B, myrotoxin C, myrotoxin D, roritoxin A, roritoxin B, and roritoxin D. In addition, the general "trichothecene" sesquiterpenoid ring structure is also present in compounds termed "baccharins" isolated from the higher plant *Baccharis megapotamica*, and these are described in the literature, for instance as disclosed by Jarvis et al. (Chemistry of Alleopathy, ACS Symposium Series No. 268: ed. A.C. Thompson, 1984, pp. 149-159) and Jarvis & Mazzola (*Acc. Chem. Res.* 15:338-395, 1982)). Trichothecenes are also produced by soil fungi of the class *Fungi imperfecti* (Bamburg, J.R. *Proc. Molec. Subcell. Biol.* 8:41-110, 1983))

[0053] "Staurosporin" includes staurosporin, a protein kinase C inhibitor of the following formula (III),

(III)

as well as diindoloalkaloids having one of the following general structures:

(IV)

(VI)

(V)

More specifically, the term "staurosporin" includes K-252 (see, for example, Japanese Patent Application No. 62,164,626), BMY-41950 (U.S. Patent No. 5,015,578), UCN-01 (U.S. Patent No. 4,935,415), TAN-999 (Japanese Pat-

ent Application No. 01,149,791), TAN-1030A (Japanese Patent Application No. 01,246,288), RK-286C (Japanese Patent Application No. 02,258,724) and functional equivalents and derivatives thereof. Derivatives of staurosporin include those discussed in Japanese Patent Application Nos. 03,72,485; 01,143,877; 02,09,819 and 03,220,194, as well as in PCT International Application Nos. WO 89 07,105 and WO 91 09,034 and European Patent Application Nos. EP 410,389 and EP 296,110. Derivatives of K-252, a natural product, are known. See, for example, Japanese Patent Application Nos. 63,295,988; 62,240,689; 61,268,687; 62,155,284; 62,155,285; 62,120,388 and 63,295,589, as well as PCT International Application No. WO 88 07,045 and European Patent Application No. EP 323,171.

[0054] As referred to herein, smooth muscle cells and pericytes include those cells derived from the medial layers of vessels and adventitial vessels which proliferate in intimal hyperplastic vascular sites following injury, such as that caused during PTCA. Characteristics of smooth muscle cells include a histological morphology (under light microscopic examination) of a spindle shape with an oblong nucleus located centrally in the cell with nucleoli present and myofibrils in the sarcoplasm. Under electron microscopic examination, smooth muscle cells have long slender mitochondria in the juxtannuclear sarcoplasm, a few tubular elements of granular endoplasmic reticulum, and numerous clusters of free ribosomes. A small Golgi complex may also be located near one pole of the nucleus. The majority of the sarcoplasm is occupied by thin, parallel myofilaments that may be, for the most part, oriented to the long axis of the muscle cell. These actin containing myofibrils may be arranged in bundles with mitochondria interspersed among them. Scattered through the contractile substance of the cell may also be oval dense areas, with similar dense areas distributed at intervals along the inner aspects of the plasmalemma.

[0055] Characteristics of pericytes include a histological morphology (under light microscopic examination) characterized by an irregular cell shape. Pericytes are found within the basement membrane that surrounds vascular endothelial cells and their identity may be confirmed by positive immuno-staining with antibodies specific for alpha smooth muscle actin (e.g., anti-alpha-sm, Biomakor, Rehovot, Israel), HMW-MAA, and pericyte ganglioside antigens e.g., MAB 3G5 (Schlingemann et al., *Am. J. Pathol.*, 136 1393 -1405 (1990)); and, negative immuno-staining with antibodies to cytokeratins (i.e., epithelial and fibroblast markers) and von Willdebrand factor (i.e., an endothelial marker). Both vascular smooth muscle cells and pericytes are positive by immunostaining with the NR-AN-0 monoclonal antibody.

[0056] As used herein, the term "procedural vascular trauma" includes the effects of surgical/mechanical interventions into mammalian vasculature, but does not include vascular trauma due to the organic vascular pathologies, i.e., diseases and infections.

[0057] Thus, procedural vascular traumas within the scope of the treatments to which medicaments, compositions, kits and devices of the invention may be applied include (1) organ transplantation, such as heart, kidney, liver and the like, e.g., involving vessel anastomosis; (2) vascular surgery, e.g., coronary bypass surgery, biopsy, heart valve replacement, atheroectomy, thrombectomy, and the like; (3) transcatheter vascular therapies (TVT) including angioplasty, e.g., laser angioplasty and PTCA procedures, employing balloon catheters, and indwelling catheters; (4) vascular grafting using natural or synthetic materials, such as in saphenous vein coronary bypass grafts, dacron and venous grafts used for peripheral arterial reconstruction, etc.; (5) placement of a mechanical shunt, e.g., a PTFE hemodialysis shunt used for arteriovenous communications; and (6) placement of an intravascular stent, which may be metallic, plastic or a biodegradable polymer. See U.S. patent application Serial No. 08/389,712, filed February 15, 1995.

[0058] For a general discussion of implantable devices and biomaterials from which they can be formed, see H. Kambic et al., "Biomaterials in Artificial Organs", *Chem. Eng. News*, 30 (April 14, 1986).

Cytoskeletal Inhibitors of use in the Present Invention

[0059] Cytoskeletal inhibitors useful in the dosage forms, medicaments, kits and pharmaceutical compositions of the invention include cytoskeletal inhibitors which biologically stent a vessel and/or reduce or inhibit vascular remodeling and/or inhibit or reduce vascular smooth muscle cell proliferation following a procedural vascular trauma. The cytoskeletal inhibitors used in the dosage forms, medicaments, kit and pharmaceutical compositions of the invention are selected to inhibit a cellular activity of a vascular smooth muscle cell, e.g., proliferation, migration, increase in cell volume, increase in extracellular matrix synthesis (e.g., collagens, proteoglycans, and the like), or secretion of extracellular matrix materials by the cell.

[0060] The therapeutic agent is a cytoskeletal inhibitors and is preferably: a) a "cytostatic agent" which acts to prevent or delay cell division in proliferating cells by inhibiting replication of DNA or by inhibiting spindle fiber formation and the like; b) an inhibitor of migration of vascular smooth muscle cells from the medial wall into the intima, e.g., an "anti-migratory agent" e.g., a cytochalasin; c) as an inhibitor of the intracellular increase in cell volume (i.e., the tissue volume occupied by a cell; a "cytoskeletal inhibitor"); d) an inhibitor that blocks cellular protein synthesis and/or secretion or organization of extracellular matrix (i.e., an "anti-matrix agent"); or any combination thereof.

[0061] Representative examples of "cytostatic agents" include, e.g., modified toxins, methotrexate, adriamycin, radionuclides (e.g., see Fritzberg et al., U.S. Patent No. 4,897,255), protein kinase inhibitors (e.g., staurosporin), taxol or analogs thereof (e.g., taxotere), inhibitors of specific enzymes (such as the nuclear enzyme DNA topoisomerase II

and DNA polymerase, RNA polymerase, adenylyl guanyl cyclase), superoxide dismutase inhibitors, terminal deoxynucleotidyl-transferase, reverse transcriptase, antisense oligonucleotides that suppress smooth muscle cell proliferation and the like, which when delivered into a cellular compartment at an appropriate dosage will act to impair proliferation of a smooth muscle cell or pericyte without killing the cell.

[0062] Representative examples of "anti-migratory agents" include inhibitors (i.e., agonists and antagonists, and competitive or non-competitive inhibitors) of chemotactic factors and their receptors (e.g., complement chemotaxins such as C5a, C5a desarg or C4a; extracellular matrix factors, e.g., collagen degradation fragments), or of intracellular cytoskeletal proteins involved in locomotion (e.g., actin, cytoskeletal elements, and phosphatases and kinases involved in locomotion). Representative examples include caffeic acid derivatives and nifedipine (a calcium antagonist), and steroid hormones. Preferred anti-migratory therapeutic agents are the cytochalasins.

[0063] Representative examples of "cytoskeletal inhibitors", a subset of cytostatic agents, include colchicine, vinblastin, cytochalasins, taxol, or analogs or derivatives thereof that act on microtubule and microfilament networks within a cell. Preferred cytoskeletal inhibitors include cytochalasin B and taxol.

[0064] Representative examples of "anti-matrix agents" include inhibitors (i.e., agonists and antagonists and competitive and non-competitive inhibitors) of matrix synthesis, secretion and assembly, organizational cross-linking (e.g., transglutaminases cross-linking collagen), and matrix remodeling (e.g., following wound healing). A representative example in this category of anti-matrix agents is colchicine, an inhibitor of secretion of extracellular matrix. Another example is tamoxifen for which evidence exists regarding its capability to organize and/or stabilize as well as diminish smooth muscle cell proliferation following angioplasty. The organization or stabilization may stem from the blockage of vascular smooth muscle cell maturation into a pathologically proliferating form.

Identification of Cytoskeletal Inhibitors Useful in the Practice of the Invention

[0065] The identification of cytoskeletal inhibitors useful in the practice of the invention may be determined by methods well known to the art. For example, a cytoskeletal inhibitor falling within the scope of the invention as described herein exhibits one or more of the following characteristics. The cytoskeletal inhibitor:

(i) results in retention of an expanded luminal cross-sectional area, diameter or volume of a vessel following angioplasty (e.g., PTCA, percutaneous transluminal angioplasty (PTA) or the like) or other trauma, including atherectomy (e.g., rotoblater, laser and the like), coronary artery bypass procedures and the like;

(ii) facilitates an initial increase in luminal cross-sectional area, diameter or volume that does not result in or accentuate chronic stenosis of the lumen;

(iii) inhibits target cell contraction or migration; and

- (iv) is cytostatic.

[0066] Methods to measure luminal cross-sectional area, volume or diameter include, but are not limited to, angiography, ultrasonic evaluation, fluoroscopic imaging, fiber optic endoscopic examination or biopsy and histology.

[0067] Preferably, a cytoskeletal inhibitor employed herein will have all four properties; however, the first and third are generally more important than the second and fourth for practice of the present invention in the methods hereinbefore described. It was found that cytochalasin B administration can result in a biological stenting effect. The biological stenting effect can be achieved using a single infusion of the therapeutic agent into the traumatized region of the vessel wall at a dose concentration ranging from about 0.1 micrograms/ml to about 10.0 micrograms/ml (Example 16).

[0068] In the case of cytoskeletal inhibitors displaying anti-migratory or anti-matrix properties, cell migration and cell adherence in *in vitro* assays, respectively, may be used for determining the concentration at which a therapeutically effective dosage will be reached in the fluid space in the vessel wall created by an infusion catheter.

[0069] A cytoskeletal inhibitor useful in the sustained release embodiments of the present invention exhibits one or more of the following characteristics. The cytoskeletal inhibitor

(i) causes the retention of an expanded luminal diameter or cross sectional area following angioplasty (e.g. PTCA, percutaneous transluminal angioplasty (PTA) or the like) or other trauma, including atherectomy (e.g. rotoblater, laser and the like), coronary artery bypass procedures or the like;

(ii) inhibits target cell proliferation (e.g. following 5 minute and 24 hour exposure to the agent, *in vitro* vascular smooth muscle tissue cultures demonstrate a level of inhibition of ³H-thymidine uptake and, preferably, display relatively less inhibition of ³H-leucine uptake);

(iii) at a dose sufficient to inhibit DNA synthesis, produces only mild to moderate (e.g., grade 2 or 3 in the assays described below) morphological cytotoxic effects;

(iv) inhibits target cell contraction; and

(v) is cytostatic.

[0070] Upon identification-of a useful cytoskeletal inhibitor exhibiting one or more-of the preceding properties, the cytoskeletal inhibitor is subjected to a second testing protocol that involves longer exposure of vascular smooth muscle cells (VSMC) to the cytoskeletal inhibitor. For example, an inhibitor useful in the sustained release embodiments of the present invention also exhibits the following characteristics:

(i) upon long term (e.g. 5 days) exposure, the inhibitor produces the same or similar *in vitro* effect on vascular smooth muscle tissue culture DNA synthesis and protein synthesis, as described above for the 5 minute and 24 hour exposures; and

(ii) at an effective dose in the long term *in vitro* assay for DNA synthesis inhibition, the inhibitor exhibits mild to moderate morphological cytotoxic effects over a longer term (e.g. 10 days).

[0071] Further evaluation of potentially useful anti-proliferative agents is conducted in an *in vivo* balloon traumatized pig femoral artery model. Preferably, these agents demonstrate a 50% or greater inhibition of cell proliferation in the tunica media vascular smooth muscle cells, as indicated by a 1 hour "BRDU flash labeling" prior to tissue collection and histological evaluation (Example 13). If an inhibitor is effective in this assay to inhibit intimal smooth muscle proliferation by 50% or more with a single exposure, it does not require administration in a sustained release dosage form.

[0072] Inhibitors are evaluated for sustained release if the systemic toxicity and potential therapeutic index appear to permit intravenous administration to achieve the 50% inhibition threshold, or if the inhibitor is amenable to local delivery to the vascular smooth muscle cells via sustained release at an effective antiproliferative dose. Inhibitors are evaluated in a sustained release dosage form for dose optimization and efficacy studies. Preferably, anti-proliferative inhibitors useful in the practice of the present invention decrease vascular stenosis by 50% in balloon traumatized pig femoral arteries and, more preferably, decrease vascular stenosis to a similar extent in pig coronary arteries.

[0073] Inhibition of cellular proliferation (i.e. DNA synthesis) is the primary characteristic of inhibitors useful in sustained release dosage forms. For example, a preferred cytoskeletal inhibitor exhibits a differential between ³H-leucine and ³Hthymidine uptake so that it can be administered at cytostatic doses. Moreover, cytotoxicity studies should indicate that prolonged exposure to the cytoskeletal inhibitors would not adversely impact the target cells. In addition, BRDU pulsing should indicate that the cytoskeletal inhibitor is effective to inhibit target cell proliferation. Any convenient method for evaluating the capability of an cytoskeletal inhibitor to inhibit cell proliferation may alternatively be employed, however.

Sustained Released Dosage Forms

[0074] Sustained release dosage form embodiments of the invention may comprise microparticles, nanoparticles or microemulsions having a cytoskeletal inhibitor dispersed therein or may comprise the cytoskeletal inhibitor in pure, preferably crystalline, solid form. For sustained release administration, microparticle dosage forms comprising pure, preferably crystalline, cytoskeletal inhibitors are preferred as described hereinbefore. The therapeutic dosage forms may be of any configuration suitable for sustained release. Preferred sustained release therapeutic dosage forms exhibit one or more of the following characteristics:

- microparticles (e.g., from about 0.01 micrometers to about 200 micrometers in diameter, preferably from about 0.5 to about 50 micrometers, and more preferably from about 2 to about 15 micrometers) or nanoparticles (e. g., from about 0.01 nanometer to about 1000 nanometers in diameter, preferably from about 50 to about 200 nanometers), free flowing powder structure comprising crystals or microcrystals;
- biodegradable structure designed to biodegrade over a period of time preferably between from about 0.5 to about 180 days, preferably from about 1 -3 to about 150 days, or non-biodegradable structure to allow therapeutic agent diffusion to occur over a time period of between from about 0.5 to about 180 days, more preferably from about 30 to about 120 days;
- biocompatible with target tissue and the local physiological environment into which the dosage form to be administered, including yielding biocompatible biodegradation products;
- facilitate a stable and reproducible dispersion of cytoskeletal inhibitor therein, preferably to form a cytoskeletal

inhibitor -polymer matrix, with active cytoskeletal inhibitor release occurring by one or both of the following routes: (1) diffusion of the cytoskeletal inhibitor through the dosage form (when the cytoskeletal inhibitor is soluble in the shaped polymer mixture defining the dimensions of the dosage form); or (2) release of the cytoskeletal inhibitor as the dosage form biodegrades; and/or

- for targeted dosage forms, having, preferably, from about 1 to about 10,000 binding protein/peptide to dosage form bonds and more preferably, a maximum of about 1 binding peptide to dosage form bond per 150 square angstroms of particle surface area. The total number of binding protein/peptide to dosage form bonds depends upon the particle size used. The binding proteins or peptides are capable of coupling to the particles of the therapeutic dosage form through covalent ligand sandwich or non-covalent modalities as set forth herein.

[0075] Nanoparticle sustained release therapeutic dosage forms are preferably biodegradable and, optionally, bind to the vascular smooth muscle cells and enter those cells, primarily by endocytosis. The biodegradation of the nanoparticles occurs over time (e.g., 30 to 120 days) in prelysosomal vesicles and lysosomes. Preferred larger microparticle therapeutic dosage form embodiments of the present invention release the cytoskeletal inhibitors for subsequent target cell uptake with only a few of the smaller microparticles entering the cell by phagocytosis. A practitioner in the art will appreciate that the precise mechanism by which a target cell assimilates and metabolizes a dosage form of the present invention depends on the morphology, physiology and metabolic processes of those cells. The size of the particle sustained release therapeutic dosage forms is also important with respect to the mode of cellular assimilation. For example, the smaller nanoparticles can flow with the interstitial fluid between cells and penetrate the infused tissue. The larger microparticles tend to be more easily trapped interstitially in the infused primary tissue, and thus are useful to deliver anti-proliferative cytoskeletal inhibitors.

[0076] Alternatively, the sustained release dosage form embodiments may comprise an emulsion or a micro emulsion having a cytoskeletal inhibitor dispersed therein. Microemulsions are generally defined as thermodynamically stable, isotropically clear dispersions of two immiscible liquids stabilized by interfacial films of surface-active molecules. Microemulsions can form spontaneously. The formation of microemulsions usually involves a combination of three to five components, namely, an oil, water, a surfactant, a cosurfactant and an electrolyte. In general, all pharmaceutical emulsions designed for parenteral administration are of the oil-in-water (o/w) type. A parenteral drug microemulsion can be useful for delivery of poorly water-soluble drugs, stabilization of hydrolytically susceptible compounds, reduction of irritation from or toxicity of intravenously administered drugs, preparation of sustained-release dosage forms, and directed delivery of drugs to various organs.

[0077] The tendency to form either a water-in-oil (w/o) or an oil-in-water (o/w) microemulsion is influenced by the properties of the oil and the surfactant. Surfactants are conveniently classified on an empirical scale known as the hydrophilic-lipophilic balance (HLB) which runs from 1 to 20. The HLB value concept of, and determination thereof for, surfactants is disclosed by Milton J. Rosen in "Surfactants & Interfacial Phenomena", J. Wiley & Sons, New York, NY, 1978, pages 242-245 or by Kirk-Othmer, Encyclopedia of Chemical Technology, 3rd Edition, Vol. 8, 1979, at pages 910-915.

[0078] In general, (w/o) microemulsions are formed using surfactants (or emulsifiers) which have an HLB value in the range of about 3 to 6 while (o/w) microemulsions are formed using surfactants which have an HLB value in the range of about 8 to 18. It has long been recognized that low interfacial tension contributes to the thermodynamic stability of microemulsions. To achieve this, the surfactant preferably exhibits low solubility in both the oil and water phases, and is preferentially absorbed at the water-oil interface with concomitant lowering of interfacial tension. When interfacial tension is less than 2×10^{-2} dyn/cm, a stable microemulsion can form. General reviews of microemulsions are provided by Bhargava et al., *Pharm. Tech.*, 46-53, March 1987 and Kahlweit, *Science*, 240, 617-621, 1988.

[0079] Microemulsions are typically substantially non-opaque, that is they are transparent or opalescent when viewed by optical microscopic means. In the undisturbed state, they are optically isotropic (non-birefringent) when examined under polarized light. The dispersed phase typically comprises particles or droplets which are normally between 5 and 200 nm in size and this gives rise to their optical transparency. These particles may be spherical although other structures are feasible.

[0080] The role of the cosurfactant, usually a short-chain alcohol, is to increase the interfacial fluidity by penetrating the surfactant film and consequently creating a disordered film due to the void space among surfactant molecules. The use of a cosurfactant in microemulsions is however optional and alcohol-free self-emulsifying emulsions and microemulsions have been described (see, for instance, Pouton et al., *Int. Journal of Pharmaceutics*, 27, 335-348, 1985 and Osborne et al., *J. Disp. Sci. Tech.*, 9, 415-423, 1988).

[0081] There are many advantages to the use of a microemulsion over a conventional emulsion (or macroemulsion) for drug transport (delivery). Microemulsions can form spontaneously, without the need for a high input of energy and are therefore easy to prepare and scale up for commercial applications; they have thermodynamic stability due to their small particle size and therefore have a long shelf life. They have an isotropically clear appearance so that they may be monitored by spectroscopic means. They have a relatively low viscosity and are therefore easy to transport and

mix. They also have a large interfacial area which accelerates surface reactions. They have a low interfacial tension which permits flexible and high penetrating power. Also, they offer the possibility of improved drug solubilization and protection against enzymatic hydrolysis. In addition, microemulsions may undergo phase inversion upon addition of an excess of the dispersed phase or in response to a temperature change and this is a property of these systems that can affect drug release from microemulsions both *in vitro* and *in vivo*.

[0082] The term "oil" is used herein in a general sense to identify a large class of substances whether of mineral, vegetable, animal, essential, synthetic or edible origin, as long as those substances are pharmaceutically acceptable. For example, tri-fatty acid esters of glycerol having about 9-83, more preferably about 21-60 and more preferably about 21-45 carbon atoms, are useful oils to prepare microemulsions. Preferred triglycerides are short chain (9-15 carbon atoms) and medium chain (21-45 carbon atoms) triglycerides. Thus, glycerol triesters includes natural, edible oils such as canola, corn, olive, sunflower and coconut oils, the decanoic esters, and chemically synthesized oils, e.g., triacetin, 1-oleyl-2,3-diacetyl glycerol and the like.

[0083] The alcohols that are useful in microemulsions include but are not limited to ethanol; propylene glycol (as $\text{CH}_2\text{OH}-\text{CH}_2-\text{CH}_2\text{OH}$ and/or $\text{CH}_3-\text{CHOH}-\text{CH}_2\text{OH}$); glycerol; C_5-C_{12} mono- and di-saccharide sugars, for example, dextrose, sucrose, fructose, in pure form, or in other forms, e.g., molasses, brown sugar, invert sugar, refinery syrup, corn syrup; and sugar alcohols such as sorbitol, xylitol and mannitol. The alcohols may be used individually or in mixtures of two or more thereof. Moreover, these alcohols are preferentially soluble in water rather than in the oils with which they are used.

[0084] The surfactants which may be useful to prepare microemulsions include all those ionic and nonionic surfactants which are useful in orally ingestible products, intended for use by humans, e.g., food, beverages, confections, pharmaceuticals and dentifrice. The selection of the surfactants for use with a particular oil depends on the HLB (hydrophile-lipophile balance) value of the surfactants.

[0085] Various ionic (anionic) surfactants include myristic acid, palmitic acid, stearic acid, oleic acid, monoglyceride ester of diacetyltartaric acid, diglyceride ester of diacetyltartaric acid, monoglyceride ester of citric acid and salts thereof, diglyceride ester of citric acid, monoglyceride ester of lactic acid, diglyceride ester of lactic acid, dioctyl sodium sulfosuccinate monoglyceride ester of phosphoric acid, diglyceride ester of phosphoric acid, lecithin, hydroxylated lecithin. Various nonionic surfactants include polysorbates, sorbitan ester of myristic acid, sorbitan ester of palmitic acid, sorbitan ester of stearic acid, sorbitan ester of oleic acid, polyglycerol esters of myristic acid, polyglycerol esters of palmitic acid, polyglycerol esters of stearic acid, polyglycerol esters of oleic acid, monoglyceride ester of myristic acid, monoglyceride ester of palmitic acid, monoglyceride ester of stearic acid, monoglyceride ester of oleic acid, diglyceride ester of myristic acid, diglyceride ester of palmitic acid, diglyceride ester of stearic acid, diglyceride ester of oleic acid, (ethoxy)_n monoglyceride of myristic acid, (ethoxy)_n monoglyceride of palmitic acid, (ethoxy)_n monoglyceride of stearic acid, (ethoxy)_n monoglyceride of oleic acid, wherein n is a whole number of 10 to 30, (ethoxy)_n diglyceride of myristic acid, (ethoxy)_n diglyceride of palmitic acid, (ethoxy)_n diglyceride of stearic acid, (ethoxy)_n diglyceride of oleic acid, wherein n is a whole number of 10 to 30, sucrose ester of myristic acid, ester of palmitic acid, ester of stearic acid, ester of oleic acid, propylene glycol ester of myristic acid, ester of palmitic acid, ester of stearic acid and ester of oleic acid.

[0086] Moreover, any of the conventional salts or surface-active derivatives can be used, provided, of course, that they are pharmaceutically acceptable. One skilled in the art can select a particular salt or derivative by conducting routine tests, if necessary. In particular, the alkali metal salts and the taurocholate derivatives are typical of such compounds.

[0087] A nonionic surfactant preferably includes an alkaline oxide condensate of an organic compound which contains one or more hydroxyl groups. For example, ethoxylated and/or propoxylated alcohols or esters or mixtures thereof are commonly available and are well known to those skilled in the art. Suitable surfactants include, but are not limited to, TYLOXAPOL; POLOXAMER 4070; POLOXAMER.188; POLYOXYL 40 Stearate; POLYSORBATE 80, and POLYSORBATE 20, as well as various compounds sold under the trade name TWEEN (ICI America, Inc., Wilmington, Del., U.S.A), and PLURONIC F - 68 (trade name of BASF, Ludwigshafen, Germany for a copolymer of polyoxyethylene and polyoxypropylene).

[0088] Some specific examples of surfactants useful in the invention can include, bile salt, sodium cholate, a mixture of 80 wt % ethyleneglycol 1000 monocetylerther and 20 wt % ethyleneglycol 400, and polyoxyethylenether. The amount of surfactant in the invention is 5-10 wt % of the total amount of case and capsule material. If the amount of surfactants is less than 0.5% wt %, the emulsion cannot be formed.

[0089] Pharmaceutical compositions comprising a microemulsion preferably also comprise a preservative, e.g., methyl-, ethyl-, propyl- and butylparaben which are medically accepted for parenteral administration. However, preservatives may not be required if the compositions can be sterilized by autoclaving without essentially reducing their stability. If desired, the pharmaceutical compositions or medicaments of the present invention can also comprise an osmotic pressure regulator such as mannitol or glycerin, glycerin being preferred for parenteral administration and mannitol for oral administration. The compositions of the present invention may also comprise an antioxidant, e.g., α -tocopherol.

[0090] The preparation of microemulsions is well known to the art. See, for example, Wolf et al. (U.S. Patent No.

4,835,002); Lee et al. (U.S. Patent No. 5,362,424); Benita et al. (U.S. Patent No. 5,364,632); Owen et al. (WO 94/08604); Constantinides (WO 94/08605); Constantinides et al. (WO 94/19000); Constantinides et al. (WO 94/190001); and Constantinides et al. (WO 94/19003).

[0091] Preferred microemulsions for use in the invention are disclosed in U.S. Patent No. 5,478,860, U.S. Patent No. 4,389,330 and U.S. Patent No. 5,407,609.

[0092] Preferred sustained release dosage form embodiments of the present invention comprise biodegradable microparticles or nanoparticles. More preferably, biodegradable microparticles or nanoparticles are formed of a polymer containing matrix that biodegrades by random, nonenzymatic, hydrolytic scissioning to release cytoskeletal inhibitor, thereby forming pores within the particulate structure.

[0093] Polymers derived from the condensation of alpha hydroxycarboxylic acids and related lactones are preferred. A particularly preferred moiety is formed of a mixture of thermoplastic polyesters (e.g., polylactide or polyglycolide) or a copolymer of lactide and glycolide components, such as poly(lactide-co-glycolide). An exemplary structure, a random poly(DL-lactide-co-glycolide), is shown below, with the values of x and y being manipulable by a practitioner in the art to achieve desirable microparticle or nanoparticle properties.

[0094] Other agents suitable for forming particulate dosage forms include polyorthoesters and polyacetals (Polymer Letters, 18:293 (1980) and polyorthocarbonates (U.S. Patent No. 4,093,709) and the like.

[0095] Preferred lactic acid/glycolic acid polymer containing matrix particles are prepared by emulsion-based processes, that constitute modified solvent extraction processes, see, for example, processes described by Cowsar et al., "Poly(Lactide-Co-Glycolide) Microcapsules for Controlled Release of Steroids," *Methods Enzymology*, 112:101-116, 1985 (steroid entrapment in microparticles); Eldridge et al., "Biodegradable and Biocompatible Poly(DL-Lactide-Co-Glycolide) Microspheres as an Adjuvant for Staphylococcal Enterotoxin B Toxin Which Enhances the Level of Toxin Neutralizing Antibodies," *Infection and Immunity*, 59:2978-2986, 1991 (toxin entrapment); Cohen et al., "Controlled Delivery Systems for Proteins Based on Poly(Lactic/Glycolic Acid) Microspheres," *Pharmaceutical Research*, 8(6):713-720, 1991 (enzyme entrapment); and Sanders et al., "Controlled Release of a Luteinizing Hormone-Releasing Hormone Analogue from Poly(D,L-Lactide-Co Glycolide) Microspheres," *J. Pharmaceutical Science*, 73(2):1294-1297, 1984 (peptide entrapment).

[0096] In general, the procedure for forming particle dosage forms involves dissolving the polymer in a halogenated hydrocarbon solvent, dispersing a cytoskeletal inhibitor solution (preferably aqueous) therein, and adding an additional agent that acts as a solvent for the halogenated hydrocarbon solvent but not for the polymer. The polymer precipitates out from the polymer/halogenated hydrocarbon solution onto droplets of the cytoskeletal inhibitor containing solution and entraps the cytoskeletal inhibitor. Preferably the cytoskeletal inhibitor is substantially uniformly dispersed within the sustained release dosage form embodiment of the present invention. Following particle formation, they are washed and hardened with an organic solvent. Water washing and aqueous nonionic surfactant washing steps follow, prior to drying at room temperature under vacuum.

[0097] For biocompatibility purposes, particulate dosage forms, characterized by a cytoskeletal inhibitor dispersed in the matrix of the particles, are sterilized prior to packaging, storage or administration. Sterilization may be conducted in any convenient manner therefor. For example, the particles can be irradiated with gamma radiation, provided that exposure to such radiation does not adversely impact the structure or function of the cytoskeletal inhibitor dispersed in the cytoskeletal inhibitor-polymer matrix or the binding protein/peptide attached thereto. If the cytoskeletal inhibitor or binding protein/peptide is so adversely impacted, the particle dosage forms can be produced under sterile conditions.

[0098] Release of the cytoskeletal inhibitor from the particle dosage form embodiments of the present invention can occur as a result of both diffusion and particle matrix erosion. The biodegradation rate directly effects the kinetics of cytoskeletal inhibitor release. The biodegradation rate is regulable by alteration of the composition or structure of the sustained release dosage form. For example, alteration of the lactide/glycolide ratio can be conducted, as described by Tice et al., "Biodegradable Controlled-Release Parenteral Systems," *Pharmaceutical Technology*, pp. 26-35, 1984; by inclusion of agents that alter the rate of polymer hydrolysis, such as citric acid and sodium carbonate, as described by Kent et al., "Microencapsulation of Water Soluble Active Polypeptides," U.S. Patent No. 4,675,189; by altering the loading of cytoskeletal inhibitor in the lactide/glycolide polymer, the degradation rate being inversely proportional to

the amount of cytoskeletal inhibitor contained therein, by judicious selection of an appropriate analog of a common family of cytoskeletal inhibitors that exhibit different potencies so as to alter said core loadings; and by variation of particle size, as described by Beck et al., "Poly(DL-Lactide-Co-Glycolide)/Norethisterone Microcapsules: An Injectable Biodegradable Contraceptive," *Biol. Reprod.*, 28:186-195, 1983, or the like. All of the aforementioned methods of regulating biodegradation rate influence the intrinsic viscosity of the polymer containing matrix, thereby altering the hydration rate thereof

[0099] The preferred lactide/glycolide structure is biocompatible with the mammalian physiological environment. Also, these preferred sustained release dosage forms have the advantage that biodegradation thereof forms lactic acid and glycolic acid, both normal metabolic products of mammals.

[0100] Functional groups required for binding of the protein/peptide to the particle dosage form are optionally included in or on the particle matrix and are attached to the non-degradable or biodegradable polymeric units. Functional groups that are useful for this purpose include those that are reactive with peptides, e.g., carboxyl groups, amine groups, sulfhydryl groups and the like. Preferred binding enhancement moieties include the terminal carboxyl groups of the preferred (lactide-glycolide) polymer containing matrix or the like.

[0101] Cytoskeletal inhibitors useful in the sustained release dosage form embodiments of the present invention preferably are those that inhibit vascular smooth muscle cell activity without killing the cells (i.e., cytostatic cytoskeletal inhibitors). A cytostatic cytoskeletal inhibitor can also be defined as a moiety capable of inhibiting one or more pathological activities of the target cells for a time sufficient to achieve a therapeutic benefit. Preferred cytoskeletal inhibitors thus exhibit one or more of the following capabilities: inhibition of DNA synthesis prior to protein synthesis inhibition, or inhibition of migration of vascular smooth muscle cells into the intima. These cytoskeletal inhibitors do not significantly inhibit protein synthesis (i.e., do not kill the target cells) and, therefore, facilitate cellular repair and matrix production, which in turn acts to stabilize the vascular wall lesion caused by angioplasty, by reducing smooth muscle cell proliferation.

[0102] Preferred cytoskeletal inhibitors are the cytochalasins, e.g., cytochalasin B (Sigma Chemical Co.), and taxol, or analogs or functional equivalents thereof. These compounds are cytostatic and have been shown to exert minimal protein synthesis inhibition and cytotoxicity at concentrations at which significant DNA synthesis inhibition occurs (see Example 8 and Figures 10A-10D). A useful protocol for identifying cytoskeletal inhibitors useful in sustained release dosage form embodiments of the present invention is set forth in Example 8, for example.

[0103] To illustrate, a cytoskeletal inhibitor, e.g., cytochalasin B, is incorporated into biodegradable poly (DL-lactide-coglycolide) microparticles or into nanoparticles. The microparticles are about 1 to about 50 μm , preferably 4 μm to about 15 μm , and more preferably about 2 to about 15 μm , in diameter. The nanoparticles are about 5 to about 500 nanometers, preferably about 10 to about 250 nanometers, and more preferably about 50 to about 200 nanometers, in diameter. The microparticles or nanoparticles comprising the cytoskeletal inhibitor can be further embedded in or on an implantable device, e.g., in a stent coating, or delivered in a suitable liquid vehicle by an implantable device, e.g., via an infusion catheter. Preferably, the sustained release dosage form is biodegradable and, preferably, biodegrades over about 30-120 days. The sustained release dosage form is preferably administered during the procedural vascular trauma.

[0104] A preferred sustained release dosage form of the invention comprises biodegradable microparticles, preferably about 2 to about 15 μm in diameter, which are tissue compatible and physically compatible with an implantable device, e.g., a needle infusion catheter or a microinfusion catheter. Another preferred sustained release dosage form of the invention comprises biodegradable nanoparticles, preferably about 50 to about 200 nanometers in diameter, which are tissue compatible and physically compatible with an implantable device, e.g., a needle infusion catheter or a microinfusion catheter. To deliver the sustained release dosage forms by catheter, catheter pore or hole sizes are preferably about 0.1 to about 8 micron, more preferably about 0.2 to about 0.8 micron, in diameter.

[0105] The cellular concentration of the cytoskeletal inhibitor that is attained in the tunica media and/or intima of the treated vessel is effective to inhibit vascular smooth muscle cell proliferation and migration, e.g., a cellular concentration at least about 0.1 $\mu\text{g/ml}$ cytochalasin B is attained. The inhibition of the smooth muscle cells results in a more rapid and complete reendothelialization after a procedural vascular trauma, e.g., intraventional placement of the stent. The increased rate of re-endothelialization reduces loss in luminal cross-sectional area or diameter and reduces decreases in blood flow

[0106] A preferred sustained release dosage form of the invention comprises a pure, solid crystalline form of a cytoskeletal inhibitor. This embodiment of the sustained release dosage form of the present invention preferably further comprises a tissue-compatible pharmaceutically acceptable matrix carrier that provides a supporting structure for the crystals, e.g., a shaped body of silicone, collagen gel retained in a collagen mesh, pluronic gel retained in a collagen mesh, or mannitol retained in a shaped body of silicone. Thus, for example, sustained release dosage forms comprising cytochalasin B and a pharmaceutical matrix carrier preferably comprise about 5 to about 70%, more preferably about 7 to about 40%, and even more preferably about 5 to about 30%, weight percent of cytochalasin B/weight percent of the total matrix carrier-therapeutic agent sustained release dosage form. Sustained release dosage forms comprising

taxol and a pharmaceutical matrix carrier preferably comprise about 1 to about 70%, more preferably about 2 to about 50%, and even more preferably about 3 to about 8%, weight percent of taxol/weight percent of the total matrix carrier-therapeutic agent sustained release dosage form. Generally sustained release dosage forms comprising a cytoskeletal inhibitor in substantially crystalline form comprise from 3 to 50, and more preferably from 5 to 40 weight percent of the dosage form.

Identification and Preparation of Targeted Dosage Forms which may be used in preparing medicaments etc. of the Invention

[0107] Vascular smooth muscle cell binding proteins useful in the invention bind to targets on the surface of vascular smooth muscle cells. A useful vascular smooth muscle binding protein is a polypeptide, peptidic, or mimetic compound (as described below) that is capable of binding to a target or marker on a surface component of an intact or disrupted vascular smooth muscle cell. Such binding allows for either release of cytoskeletal inhibitors extracellularly in the immediate interstitial matrix with subsequent diffusion of cytoskeletal inhibitor into the remaining intact smooth muscle cells and/or internalization by the cell into an intracellular compartment of the entire targeted biodegradable moiety, thus permitting delivery of the cytoskeletal inhibitor thereto. It will be recognized that specific targets, e.g., polypeptides or carbohydrates, proteoglycans and the like, that are associated with the cell membranes of vascular smooth muscle cells are useful for selecting (e.g., by cloning) or constructing (e.g., by genetic engineering or chemical synthesis) appropriately specific vascular smooth muscle binding proteins. Particularly useful "targets" are internalized by smooth muscle cells, e.g., as membrane constituent antigen turnover occurs in renewal. Internalization by cells may also occur by mechanisms involving phagolysosomes, clathrin-coated pits, receptor-mediated redistribution or endocytosis and the like.

[0108] --Representative examples of useful vascular smooth muscle binding proteins include antibodies (e.g., monoclonal and polyclonal antibodies), F(ab')₂, Fab', Fab, and Fv fragments and/or complementarity determining regions (CDR) of those antibodies or functional equivalents thereof, (e.g., binding peptides and the like); growth factors, cytokines, and polypeptide hormones and the like; and macromolecules recognizing extracellular matrix receptors (e.g., integrin and fibronectin receptors and the like).

[0109] In a preferred embodiment, e.g., a "target" is exemplified by chondroitin sulfate proteoglycans (CSPGs) synthesized by vascular smooth muscle cells and pericytes, and a discrete portion (termed an epitope herein) of the CSPG molecule having an apparent molecular weight of about 250 kD is especially preferred as a target. The 250 kD target is an N-linked glycoprotein that is a component of a larger 400 kD proteoglycan complex (Bumol et al., PNAS USA, 79:1245-1249 (1982)). In one presently preferred embodiment of the invention, a vascular smooth muscle binding protein is provided by the NR-AN-01 monoclonal antibody (a subculture of NR-ML-05) that binds to an epitope in a vascular smooth muscle CSPG target molecule. The monoclonal antibody designated NR-ML-05 reportedly binds a 250 kD CSPG synthesized by melanoma cells (Morgan et al., U.S. Patent No. 4,897,255).

[0110] Smooth muscle cells and pericytes also reportedly synthesize a 250 kD CSPG as well as other CSPGs (Schlingeman et al., supra). NR-ML-05 binding to smooth muscle cells has been disclosed (Fritzberg et al., U.S. Patent No. 4,879,225). The hybridoma, NR-ML-05, which secretes a monoclonal antibody which binds to the 400 kD CSPG, has been deposited with the American Type Culture Collection, Rockville, MD and granted Accession No. 9350. NR-ML-05 is the parent of and structurally and functionally equivalent to, subclone NR-AN-0 1, disclosed herein.

[0111] It will be recognized that NR-AN-0 1 is just one example of a vascular smooth muscle binding protein that specifically associates with the 400 kD CSPG target, and that other binding proteins associating with this target and other epitopes on this target (Bumol et al., PNAS USA, 79:1245-1249 (1982)) are also useful in the medicaments, compositions, devices, kits of the invention when the medicaments, compositions, devices or kits are used for treating stenosis following vascular surgical procedures, e.g., PTCA, preferred binding proteins, e.g., antibodies or fragments, for use in the practice of the invention have a binding affinity of $> 10^4$ liter/mole for the vascular smooth muscle 250 kD CSPG, and also the ability to be bound to and internalized by smooth muscle cells or pericytes.

[0112] Further, it will be recognized that the amino acid residues involved in the multipoint kinetic association of the NR-AN-01 monoclonal antibody with a CSPG marker antigenic epitope (i.e., the amino acids constituting the complementarity determining regions) can be determined by computer-assisted molecular modeling and by the use of mutants having altered antibody binding affinity. The binding-site amino acids and three dimensional model of the NR-AN-01 antigen binding site can serve as a molecular model for constructing functional equivalents, e.g., short polypeptides ("minimal polypeptides"), that have binding affinity for a CSPG synthesized by vascular smooth muscle cells and pericytes.

[0113] Three-dimensional modeling is also useful to construct other functional equivalents that mimic the binding of NR-AN-01 to its antigenic epitope, e.g., "mimetic" chemical compounds that mimic the three-dimensional aspects of NR-AN-01 binding to its epitope in a CSPG target antigen. As used herein, "minimal polypeptide" refers to an amino acid sequence of at least six amino acids in length. As used herein, the term "mimetic" refers to an organic chemical

oligomer or polymer constructed to achieve the proper spacing for binding to the amino acids of, for example, an NR-AN-01 CSPG target synthesized by vascular smooth muscle cells or pericytes.

[0114] It is also envisioned that human monoclonal antibodies or "humanized" murine antibodies which bind to a vascular smooth muscle binding protein are useful in the therapeutic conjugates. For example, murine monoclonal antibody may be "chimerized" by genetically recombining the nucleotide sequence encoding the murine Fv region (i. e., containing the antigen binding sites) with the nucleotide sequence encoding a human constant domain region and an Fc region, e.g., in a manner similar to that disclosed in European Patent Application No. 411,893. Some murine residues may also be retained within the human variable region framework domains to ensure proper target site binding characteristics. Humanized vascular smooth muscle binding partners will be recognized to have the advantage of decreasing the immunoreactivity of the antibody or polypeptide in the host recipient, and may be useful for increasing the *in vivo* half-life and reducing the possibility of adverse immune reactions to the conjugate.

[0115] Also contemplated as useful binding peptides for sustained release dosage forms adapted for restenosis treatment are those that localize to intercellular stroma and matrix located between and among vascular smooth muscle cells. Such binding peptides can deliver the cytoskeletal inhibitor to the interstitial space between the target cells. The cytoskeletal inhibitor is released into the interstitial spaces for subsequent uptake by the vascular smooth muscle cells. Preferred binding peptides of this type are associated with epitopes on collagen, extracellular glycoproteins, e.g., tenascin, reticulum and elastic fibers, cytokeratin and other intercellular matrix components. Minimal peptides, mimetic organic chemical compounds, human or humanized monoclonal antibodies and the like that localize to intracellular stroma and matrix are also useful as binding peptides in this embodiment of the present invention. These binding peptides may be identified and constructed or isolated in accordance with known techniques. In preferred embodiments of the present invention, the interstitial matrix binding protein binds to a target epitope with an association constant of at least about 10^{-4} M.

[0116] Representative "coupling" methods for linking the cytoskeletal inhibitor through covalent or non-covalent bonds to the vascular smooth muscle binding protein include chemical cross-linkers and heterobifunctional cross-linking compounds (i.e., "linkers") that react to form a bond between reactive groups (such as hydroxyl, amino, amido, or sulfhydryl groups) in a cytoskeletal inhibitor and other reactive groups (of a similar nature) in the vascular smooth muscle binding protein. This bond may be, for example, a peptide bond, disulfide bond, thioester bond, amide bond, thioether bond, and the like.

[0117] In one illustrative example, conjugates of monoclonal antibodies with drugs have been summarized by Morgan and Foon (Monoclonal Antibody Therapy to Cancer: Preclinical Models and Investigations, Basic and Clinical Tumor Immunology, Vol. 2, Kluwer Academic Publishers, Hingham, MA) and by Uhr J. of Immunol. 12:i-vii, 1984). In another illustrative example where the conjugate contains a radionuclide cytostatic agent, U.S. Patent No. 4,897,255, Fritzberg et al., is instructive of coupling methods that can be used to make the present conjugates.

[0118] The choice of coupling method will be influenced by the choice of vascular smooth muscle binding protein or peptide, interstitial matrix binding protein or peptide and cytoskeletal inhibitor, and also by such physical properties as, e.g., shelf life stability, and/or by biological properties, e.g., half-life in cells and blood, intracellular compartmentalization route, and the like.

[0119] The physical and chemical character of the sustained release dosage form embodiments of the present invention permit several alternative modes of attachment of the dosage forms to binding proteins or peptides. Dosage forms (sustained release-type) as described herein are capable of binding to binding proteins/peptides through, for example, covalent linkages, intermediate ligand sandwich attachment, or non-covalent adsorption or partial entrapment. When the preferred poly-lactic/glycolic acid particles are formed with the cytoskeletal inhibitor dispersed therein, the uncharged polymer backbone is oriented both inward (with the quasi lipophilic therapeutic agent contained therein) and outward, along with a majority of the terminal carboxy groups. These surface carboxy groups may serve as covalent attachment sites when activated by, for example, a carbodiimide) for nucleophilic groups of the binding protein/peptide. Such nucleophilic groups include lysine epsilon-amino groups (amide linkage), serine hydroxyl groups (ester linkage) or cysteine mercaptan groups (thioester linkage). Reactions with particular groups depend upon pH and the reduction state of the reaction conditions.

[0120] For example, poly-lactic/glycolic acid particles having terminal carboxylic acid groups can be reacted with N-hydroxybenzotriazole in the presence of a water soluble carbodiimide of the formula $R-N=C=N-R'$ (wherein R is a 3-dimethylaminopropyl group or the like and R' is an ethyl group or the like). The benzotriazole-derivatized particles (i. e., activated imidate-bearing moieties) are then reacted with a protein/peptide nucleophilic moiety such as an available epsilon-amino moiety. Alternatively, p-nitrophenol, tetrafluorophenol, N-hydroxysuccinimide or like molecules are useful to form an active ester with the terminal carboxy groups of poly-lactic/glycolic acid particles in the presence of carbodiimide. Other binding protein/peptide nucleophilic moieties include hydroxyl groups of serine, endogenous free thiols of cysteine, thiol groups resulting from reduction of binding protein/peptide disulfide bridges using reducing agents commonly employed for that purpose (e.g., cysteine, dithiothreitol, mercaptoethanol and the like) and the like. Additionally, the terminal carboxy groups of the poly-lactic/glycolic acid particles are activatable by reaction with thionyl

chloride to form an acyl chloride derivatized moiety. The derivatized particles are then reacted with binding peptide/protein nucleophilic groups to form targeted dosage forms.

[0121] Direct conjugation of sustained release dosage form to binding protein or peptide may disrupt binding protein/peptide recognition of the target cell. Ligand sandwich attachment techniques are useful alternatives to achieve sustained release dosage form attachment to binding protein/peptide. These techniques involve the formation of a primary peptide or protein shell using a protein that does not bind to the target cell population. Binding protein/peptide is then bound to the primary peptide or protein shell to provide the resultant particle with functional binding protein/peptide. An exemplary ligand sandwich approach involves covalent attachment of avidin or streptavidin to the particles through functional groups as described above with respect to the "direct" binding approach. The binding protein or peptide is derivatized, preferably minimally, via functionalized biotin (e.g., through active ester, hydrazide, iodoacetal, maleimidyl or like functional groups). Ligand (i.e., binding peptide or protein/ functionalized biotin) attachment to the available biotin binding sites of the avidin/streptavidin primary protein shell occurs through the use of a saturating amount of biotinylated protein/peptide.

[0122] For example, poly-lactic/glycolic acid particles having terminal carboxylic acid groups are activated with carbodiimide and subsequently reacted with avidin or streptavidin. The binding protein or peptide is reacted with biotinamidocaproate N-hydroxysuccinimide ester at a 1-3 molar offering of biotin-containing compound to the binding protein/peptide to form a biotinylated binding protein/peptide. A molar excess of the biotinylated binding protein/peptide is incubated with the avidin-derivatized particles to form a targeted dosage form.

[0123] Alternatively, the particle carboxy groups are biotinylated (e.g., through carbodiimide activation of the carboxy group and subsequent reaction with amino alkyl biotinamide). The biotinylated particles are then incubated with a saturating concentration (i.e., a molar excess) of avidin or streptavidin to form protein coated particles having free biotin binding sites. These coated particles are then capable of reaction with a molar excess of biotinylated binding protein formed as described above. Another option involves avidin or streptavidin bound binding peptide or protein attachment to biotinylated particles.

[0124] In addition, binding protein/peptide-particle attachment can be achieved by adsorption of the binding peptide to the particle, resulting from the nonionic character of the partially exposed polymer backbone of the particle. Under high ionic strength conditions (e.g., 1.0 molar NaCl), hydrogen and hydrophobic particle-binding protein/peptide binding are favored.

[0125] Moreover, binding protein/peptide may be partially entrapped in the particle polymeric matrix upon formation thereof. Under these circumstances, such entrapped binding protein/peptide provides residual selective binding character to the particle. Mild particle formation conditions, e.g., those employed by Cohen et al., *Pharmaceutical Research*, 8: 713-720 (1991), are preferred so as to entrap the protein or peptide in the matrix. Entrapped binding proteins are also useful in target cell reattachment of a partially degraded particle that has undergone exocytosis. Binding proteins or peptides can be bound to other polymeric particle dosage forms (e.g., non-biodegradable dosage forms) having different exposed functional groups in accordance with the principles discussed above.

[0126] Exemplary non-biodegradable polymers useful in the practice of the present invention are polystyrenes, polypropylenes, styrene acrylic acid and acrylate copolymers and the like. Such non-biodegradable polymers incorporate or can be derivatized to incorporate functional groups for attachment of binding protein/peptide, including carboxylic acid groups, aliphatic primary amino groups, aromatic amino groups and hydroxyl groups.

[0127] Carboxylic acid functional groups are coupled to binding protein or peptide using, for example, the reaction mechanisms set forth above for poly-lactic/glycolic acid biodegradable polymeric particle dosage forms. Primary amino functional groups are coupled by, for example, reaction thereof with succinic anhydride to form a terminal carboxy moiety that can be bound to binding peptide/protein as described above. Additionally, primary amino groups can be activated with cyanogen bromide and form guanidine linkages with binding protein/peptide primary amino groups. Aromatic amino functional groups are, for example, diazotized with nitrous acid to form diazonium moieties which react with binding protein/peptide tyrosines, thereby producing a diazo bond between the non-biodegradable particle and the binding protein/peptide. Hydroxyl functional groups are coupled to binding protein/peptide primary amino groups by, for example, converting the hydroxyl moiety to a moiety comprising a terminal carboxylic acid functional group. This conversion can be accomplished through reaction with chloroacetic acid followed by reaction with carbodiimide. Sandwich, adsorption and entrapment techniques, discussed above with respect to biodegradable particles, are analogously applicable to nonbiodegradable particle-binding protein/peptide affixation.

Dosages; Formulabon and Routes of Administration of the Cytoskeletal Inhibitors

[0128] The amount of cytoskeletal inhibitor administered is adjusted to treat vascular traumas of differing severity. For example, smaller doses are sufficient to treat lesser vascular trauma, e.g., to prevent vascular rejection following graft or transplant, while larger doses are sufficient to treat more extensive vascular trauma, e.g., to treat restenosis following angioplasty. Thus, to biologically stent a traumatized vessel a cytoskeletal inhibitor such as cytochalasin B

is administered at a systemic total dose of about 1 to about 24 ml, preferably about 1 to about 4 ml, at about 0.01 to about 10 μg cytochalasin B/ml of vehicle, preferably about 0.1 to about 10 μg cytochalasin B/ml of vehicle, and more preferably about 0.1 to about 8.0 μg cytochalasin B/ml of vehicle, although other dosages may prove beneficial. In particular, lower concentrations of a cytochalasin may exert a therapeutic effect when a non-aqueous solvent is employed as the vehicle. The administration of a systemic dose of cytochalasin B results in about 5 to about 40, preferably about 8 to about 30, λ of the cytochalasin B-containing solution entering the interstitial space surrounding the cells of the tunica media, and about 0.01 to about 4, preferably about 0.05 to about 3, ml of the solution being exposed to the wall of the vessel by the transport of the solution to the adventitia. Moreover, these dosages may also exhibit anti-proliferative effects.

[0129] Administration of medicaments, compositions, or dosage forms of the present invention may be continuous or intermittent, depending, for example, upon the recipient's physiological condition, whether the purpose of the administration is therapeutic or prophylactic, and other factors known to skilled practitioners. The administration of the medicaments, compositions or dosage forms of the invention may be essentially continuous over a preselected period of time or may be in a series of spaced doses, e.g., either before, during, or after procedural vascular trauma, before and during, before and after, during and after, or before, during and after the procedural vascular trauma. Moreover, the administration of the medicaments, compositions or dosage forms is selected so as to not further damage the traumatized vessel.

[0130] One or more suitable unit dosage forms comprising the cytoskeletal inhibitor, which may be formulated for sustained release, can be administered by a variety of routes including oral, or parenteral, including by rectal, transdermal, subcutaneous, intravenous, intramuscular, intrapulmonary and intranasal routes: When the medicaments, compositions and dosage forms of the invention are prepared for oral administration, they preferably combined with a pharmaceutically acceptable carrier, diluent or excipient to form a pharmaceutical formulation preferably in unit dosage form. The total active ingredients in these formulations can comprise from 0.1 to 99.9% by weight of the formulation. By "pharmaceutically acceptable" it is meant the carrier, diluent, excipient, and/or salt must be compatible with the other ingredients of the formulation, and not deleterious to the recipient thereof.

[0131] Pharmaceutical formulations containing the cytoskeletal inhibitor can be prepared by procedures known in the art using well known and readily available ingredients. For example, a cytochalasin can be formulated with common excipients, diluents, or carriers, and formed into tablets, capsules, suspensions, powders, and the like. Examples of excipients, diluents, and carriers that are suitable for such formulations include the following fillers and extenders, e.g., starch, sugars, mannitol, and silicic derivatives; binding agents, for example, carboxymethyl cellulose, HPMC, and other cellulose derivatives, alginates, gelatin, and polyvinyl-pyrrolidone; moisturizing agents such as glycerol; disintegrating agents, e.g., calcium carbonate and sodium bicarbonate; agents for retarding dissolution, for example, paraffin; resorption accelerators such as quaternary ammonium compounds; surface active agents, e.g., cetyl alcohol, glycerol monostearate; adsorptive carriers such as kaolin and bentonite; and lubricants, for example, talc, calcium and magnesium stearate, and solid polyethyl glycols. See Fondy et al. (WO 88/10259).

[0132] For example, tablets or caplets containing a cytoskeletal inhibitor can include buffering agents, e.g., calcium carbonate, magnesium oxide and magnesium carbonate. Caplets and tablets can also include inactive ingredients such as cellulose, pregelatinized starch, silicon dioxide, hydroxypropyl methylcellulose, magnesium stearate, microcrystalline cellulose, starch, talc, titanium dioxide, benzoic acid, citric acid, corn starch, mineral oil, polypropylene glycol, sodium phosphate, and zinc stearate, and the like. Hard or soft gelatin capsules containing a cytoskeletal inhibitor can contain inactive ingredients, for example, gelatin, microcrystalline cellulose, sodium lauryl sulfate, starch, talc, and titanium dioxide, and the like, as well as liquid vehicles such as polyethylene glycols (PEGs) and vegetable oil.

[0133] Cytoskeletal inhibitors can also be formulated as elixirs or solutions for convenient oral administration or as solutions appropriate for parenteral administration, for instance by intramuscular, subcutaneous or intravenous routes. In the practice of certain embodiments of the present invention, the cytoskeletal inhibitor is dispersed in a pharmaceutically acceptable carrier that is in liquid phase, and delivered via an implantable device, e.g., a catheter. Useful pharmaceutically acceptable carriers for these purposes include generally employed carriers, such as phosphate buffered saline solution, water, emulsions (e.g., oil/water and water/oil emulsions) and wetting agents of various types.

[0134] The pharmaceutical formulations of the cytoskeletal inhibitors can take the form of an aqueous or anhydrous solution or dispersion, or alternatively the form of an emulsion or suspension. See Fondy et al. (WO90/13293).

[0135] These formulations can contain pharmaceutically acceptable vehicles and adjuvants which are well known in the prior art. It is possible, for example, to prepare solutions using one or more organic solvent(s) that is/are acceptable from the physiological standpoint, chosen, in addition to water, from solvents, e.g., acetone, ethanol, isopropyl alcohol, glycol ethers such as the products sold under the name "Dowanol", polyglycols and polyethylene glycols, C₁-C₄ alkyl esters of short-chain acids, preferably ethyl or isopropyl lactate, fatty acid triglycerides, for example products marketed under the name "Miglyol", isopropyl myristate, animal, mineral and vegetable oils and polysiloxanes.

[0136] The compositions and medicaments according to the invention can also contain thickening agents such as cellulose and/or cellulose derivatives. They can also contain gums, e.g., xanthan, guar or carbo gum or gum arabic,

or alternatively polyethylene glycols, bentones and montmorillonites, and the like.

[0137] It is possible to add, if necessary, an adjuvant chosen from antioxidants, surfactants, other preservatives, film-forming, keratolytic or comedolytic agents, perfumes and colorings. Also, other active ingredients may be added, whether for the conditions described or some other condition.

[0138] For example, among antioxidants, t-butylhydroquinone, butylated hydroxyanisole, butylated hydroxytoluene and a-tocopherol and its derivatives may be mentioned. The galenical forms chiefly conditioned for topical application take the form of creams, milks, gels, dispersion or microemulsions, lotions thickened to a greater or lesser extent, impregnated pads, ointments or sticks, or alternatively the form of aerosol formulations in spray or foam form or alternatively in the form of a cake of soap.

[0139] Additionally, cytoskeletal inhibitors are well suited to formulation as sustained release dosage forms and the like. The formulations can be so constituted that they release the active ingredient only or preferably in a particular part of the intestinal tract, e.g., over a period of time. The coatings, envelopes, and protective matrices may be made, for example, from polymeric substances or waxes.

[0140] The local delivery of the cytoskeletal inhibitors can be by a variety of techniques which administer the agent at or near the traumatized vascular site. Examples of site-specific or targeted local delivery techniques are not intended to be limiting but to be illustrative of the techniques available. Examples include local delivery catheters, such as an infusion catheter, an indwelling catheter, or a needle catheter, stents, synthetic grafts, adventitial wraps, shunts and stents or other implantable devices, site specific carriers, direct injection, or direct applications.

[0141] Local delivery by an implant describes the surgical placement of a matrix that contains the cytoskeletal inhibitor into the lesion or traumatized area. The implanted matrix releases the cytoskeletal inhibitor by diffusion, chemical reaction, or solvent activators. See, for example, Lange, *Science*, 249, 1527 (1990).

[0142] An example of targeted local delivery by an implant is the use of a stent. Stents are designed to mechanically prevent the collapse and reocclusion of the coronary arteries or other vessels. Incorporation of a cytoskeletal inhibitor into the stent can deliver the cytoskeletal inhibitor directly to the lesion. Local delivery of agents by this technique is described in Koh, *Pharmaceutical Technology* (October, 1990).

[0143] For example, a metallic, plastic or biodegradable intravascular stent is employed which comprises the cytoskeletal inhibitor. The stent preferably comprises a biodegradable coating, a porous or a permeable non-biodegradable coating, or a biodegradable or non-biodegradable membrane or synthetic graft sheath like coating, e.g., PTFE, comprising the cytoskeletal inhibitor. A more preferred embodiment of the invention is a coated stent wherein the coating comprises a sustained-release dosage form of the cytoskeletal inhibitor. In an alternative embodiment, a biodegradable stent may also have the therapeutic agent impregnated therein, i.e., in the stent matrix.

[0144] A biodegradable stent with the cytoskeletal inhibitor impregnated therein can be further coated with a biodegradable coating or with a porous non-biodegradable coating having the sustained release-dosage form of the cytoskeletal inhibitor dispersed therein. This stent can provide a differential release rate of the cytoskeletal inhibitor, i.e., there can be an initial faster release rate of the cytoskeletal inhibitor from the coating, followed by delayed release of the cytoskeletal inhibitor impregnated in the stent matrix, upon degradation of the stent matrix. The intravascular stent also provides a mechanical means of providing an increase in luminal area of a vessel. Furthermore, the placement of intravascular stents comprising a cytoskeletal inhibitor which is an inhibitor of smooth muscle cell proliferation can also reduce or prevent intimal proliferation. This inhibition of intimal smooth muscle cells and stroma produced by the smooth muscle and pericytes can lead to a more rapid and complete re-endothelization following the intravascular placement of the vascular stent. The increased rate of re-endothelization and stabilization of the vessel wall following stent placement can reduce the loss of luminal area and decreased blood flow due to vascular smooth muscle cell proliferation which is one of the primary causes of vascular stent failures.

[0145] Another example of targeted local delivery by an implant is the use of an adventitial wrap. The wrap comprises a pharmaceutically acceptable carrier matrix, e.g., a Pluronic gel which is free, or contained by a collagen mesh, which gel has dispersed therein a cytoskeletal inhibitor. One embodiment of the invention is a pluronic gel (F-127, BASF) which is soluble at 4°C but solidifies at 37°C, e.g., on contact with fluid or tissue in a human. To prepare a pluronic gel containing wrap, 4 ml of phosphate buffer, pH 7.0 (*CircRes*, vol. 76, April 1995), was added to 1 g of pluronic gel F-127, which was mixed overnight at 4°C. The cytoskeletal inhibitor was added to the mixture prior to local administration. The mixture may be applied directly to a surgically exposed artery wall, or may be applied to the surface of a bovine collagen mat (BioCore, Inc., Topeka, KS), which is then wrapped around the artery and the edges joined by sutures.

[0146] Another embodiment of the invention is the incorporation of the cytoskeletal inhibitor into the expanded nodal spaces of a PTFE (Impra, Inc., Tempe, AZ) vascular graft-like membrane which can surround, or be placed on the interior or on the exterior surface of, an interluminal vascular stent, which comprises metal or a biodegradable or nonbiodegradable polymer. The cytoskeletal inhibitor, or a sustained release dosage form of the cytoskeletal inhibitor, fills the nodal spaces of the PTFE membrane wall and/or coats the inner and/or outer surfaces of the membrane.

[0147] Yet another embodiment of the invention is a mixture of a crystalline form of a cytoskeletal inhibitor in a bovine collagen gel (BioCore, Inc., Topeka, KS). Crystals varied in size from about 0.1 micron to about 1 mm. Generally, the

crystals were pulverized to generate smaller sized crystals. This mixture is applied directly to the surface of the artery, and the surrounding subcutaneous tissues sutured around the vessel and the skin closed. Bovine collagen (BioCore, Inc., Topeka, KS) is dissolved in sterile saline (1:1) and the crystalline cytoskeletal inhibitor added. Alternatively, the collagen gel is applied to a bovine collagen mesh which is then wrapped around the vessel and the edges sutured to hold the mesh in place. The bovine collagen mesh (BioCore, Inc.) is cut to size, e.g., 1 cm x 1 cm, and the cytoskeletal inhibitor-collagen gel mixture is applied to the surface of the mesh.

[0148] A further embodiment of the invention comprises the entrapment of crystalline cytoskeletal inhibitor in about a 0.1 to about 3, preferably about 0.5 to about 0.7, mm thick silicone membrane, e.g., silicone polymer Q-7 4840 (Dow Corning, Midland, MI). The polymer (part A and B, 1:1) is mixed with a spatula. An inert filler, e.g., mannitol, is powdered and sieved to a fraction 53-75 mesh size. Mannitol and cytoskeletal inhibitor are mixed in predetermined proportions and then levigated with the polymer to form a composite. The composite is filled in a slab mold and compressed to 5000 psi. The composite is then cured at 80°C for 2 hours. The composite membrane is then cut to size, e.g., 1 cm x 1 cm, wrapped around the artery and held in place by suturing the membrane edges together.

[0149] A cytoskeletal inhibitor may also be coated onto the exterior of the wrap. The wrap and/or the coating is preferably biodegradable. It is preferred that the cytoskeletal inhibitor is in sustained release dosage form.

[0150] Another example is a delivery system in which a polymer that contains the cytoskeletal inhibitor is injected into the area of the lesion in liquid form. The polymer then solidifies or cures to form the implant which is retained *in situ*. This technique is described in PCT WO 90/03768 (Donn, Apr. 19, 1990).

[0151] Another example is the delivery of a cytoskeletal inhibitor by polymeric endoluminal sealing. This technique uses a catheter to apply a polymeric implant to the interior surface of the lumen. The cytoskeletal inhibitor incorporated into the biodegradable polymer implant and is thereby released at the surgical site. The technique is described in PCT WO 90/01969 (Schindler, Aug. 23, 1989).

[0152] Yet another example of local delivery is by direct injection of vesicles or microparticles into the lesion or artery wall adjacent to the lesion. These microparticles may be composed of substances such as proteins, lipids, carbohydrates or synthetic polymers. These microparticles have the cytoskeletal inhibitor incorporated throughout the microparticle or onto the microparticle as a coating. Delivery systems incorporating microparticles are described in Lange, *Science*, 249, 1527 (1990) and Mathiowitz et al., *J App. Poly. Sci.*, 26, 809 (1981).

[0153] For topical administration, the therapeutic agents may be formulated as is known in the art for direct application to a target area. Conventional forms for this purpose include wound dressings, coated bandages or other polymer coverings, ointments, lotions, pastes, jellies, sprays, and aerosols. The percent by weight of a cytoskeletal inhibitor present in a topical formulation will depend on various factors, but generally will be from 0.005% to 95% of the total weight of the formulation, and typically 1-25% by weight.

Conditions Amenable to Treatment by the Medicament, Compositions, Kit or Dosage Forms of the Invention

[0154] The medicaments, kits, compositions and dosage forms as described hereinbefore are useful to treat or inhibit a diminution in vessel lumen volume, area and/or diameter associated with a procedural vascular trauma. As used herein, "vessels" includes mammalian vessels, e.g., coronary vessels as well as peripheral, femoral and carotid vessels. It will be recognized that the medicaments, compositions, kits and dosage forms (both free and sustained release) of the invention are not restricted in use for therapy following angioplasty; rather, the usefulness of the medicaments, compositions, kits and dosage forms will be proscribed by their ability to inhibit cellular activities of smooth muscle cells and pericytes in the vascular wall. Thus, a vascular trauma includes but is not limited to trauma associated with an interventional procedure, such as angioplasty, placement of a stent, shunt, stent, synthetic or natural graft, adventitial wrap, indwelling catheter or other implantable devices. Grafts include synthetic therapeutic agent-treated grafts, e.g., impregnated or coated grafts.

[0155] The medicaments, compositions, kits and dosage forms of the invention are also useful in therapeutic modalities for enhancing the regrowth of endothelial cells in injured vascular tissues and in other wound sites including epithelial wounds. In these therapeutic modalities, the medicaments, compositions, kits and dosage forms of the invention and conjugates as described herein find utility in inhibiting the migration and/or proliferation of smooth muscle cells or pericytes. Smooth muscle cells and pericytes have been implicated in the production of factors *in vitro* that inhibit endothelial cell proliferation, and their proliferation can also result in a physical barrier to establishing a continuous endothelium. Thus, the medicaments, compositions, kits and dosage forms of the invention and conjugates described herein find utility in promoting neo-angiogenesis and increased re-endothelialization, e.g., during wound healing, vessel grafts and following vascular surgery. The dosage forms may also release therapeutic modalities that stimulate or accelerate up re-endothelialization of the damaged vessel wall.

[0156] In some embodiments of the present invention a cytoskeletal inhibitor capable of inhibiting the ability of vascular smooth muscle cells to contract may be used, e.g. a cytochalasin. Exemplary cytoskeletal inhibitors useful in the practice of this aspect of the present invention are those capable of causing a traumatized artery to lose vascular tone,

such that normal vascular hydrostatic pressure (i.e., blood pressure) expands the flaccid vessel to or near to its maximal physiological diameter. Loss of vascular tone may be caused by cytoskeletal inhibitors that interfere with the formation or function of contractile proteins (e.g., actin, myosin, tropomyosin, caldesmon, calponin or the like). This interference can occur directly or indirectly through, for example, inhibition of calcium modulation, phosphorylation or other metabolic pathways implicated in contraction of vascular smooth muscle cells.

[0157] Inhibition of cellular contraction (i.e., loss of vascular tone) may operate through two mechanisms to reduce the degree of vascular stenosis. First, inhibition of cellular contraction for a prolonged period of time limits the number of smooth muscle cells that migrate from the tunica media into the intima, the thickening of which results in vascular luminal stenosis. Second, inhibition of cellular contraction causes the smooth muscle wall to relax and dilate under normal vascular hydrostatic pressure (i.e., blood pressure).

[0158] The cytochalasins inhibit smooth muscle cell contraction without abolishing the protein synthesis necessary for traumatized, post-angioplasty or other surgically- or disease-damaged, smooth muscle cells to repair themselves. Protein synthesis is also necessary for the smooth muscle cells to secrete matrix, which fixes or retains the lumen in a state near its maximum systolic diameter as the vascular lesion stabilizes (i.e., a biologically induced stenting effect).

[0159] This biological stenting effect not only results in an expanded vessel luminal cross-sectional area or diameter and increased blood flow rate through the vessel, but also significantly reduces elastic recoil following angioplasty. Elastic recoil is an acute closure of the vessel associated with vasospasm or early relaxation of the muscular wall, due to trauma shock resulting from vessel overstretching by a balloon catheter during angioplasty. This spasm of the tunica media which leads to decreases in the luminal cross-sectional area may occur within hours, days or weeks after the balloon dilation, as restoration of vascular muscle wall tone occurs.

[0160] Recent observations during microscopic examination of atheroectomy specimens suggest that elastic recoil may occur in up to 25% of angioplasty procedures classified as successful, based on the initial post-procedure angiogram. Because the biological stenting procedure relaxes the artery wall following balloon angioplasty, the clinician can eliminate over-inflation and its resultant trauma shock as a means to diminish or delay the vessel spasm or elastic recoil. Reduction or elimination of over-inflation decreases trauma to the muscular wall of the vessel, thereby reducing the determinants of smooth muscle cell proliferation in the intima and, therefore, reducing the incidence or severity of restenosis.

[0161] Biological stenting also decreases the incidence of thrombus formation. In pig femoral arteries treated with cytochalasin B, for example, the incidence of mural microthrombi was decreased as compared to the balloon traumatized arteries that were not treated with the cytoskeletal inhibitor. This phenomenon appears to be a secondary benefit that may result from the increased blood flow through the traumatized vessel, said benefit being obtained by the medicaments, compositions, kits, dosage forms and devices of the present invention. In arteries treated with sustained release dosage forms of cytochalasin B, cytochalasin-B may also prevent the contraction and organization of platelets which is required for thrombus formation.

[0162] Cytochalasins are capable of generating a biological stenting effect on vascular smooth muscle cells. Cytochalasins are thought to inhibit both migration and contraction of vascular smooth muscle cells by interacting with actin. The cytochalasins interact with the ends of filamentous actin to inhibit the elongation of the actin filaments. Low doses of cytochalasins (e.g., cytochalasin B) also disrupt microfilament networks of actin. *In vitro* data indicate that after vascular smooth muscle cells clear cytochalasin B, the cells regenerate enough polymerized actin to resume migration within about 24 hours. *In vitro* assessments reveal that vascular smooth muscle cells regain vascular tone within 2 to 4 days. It is during this recuperative period that the lumen diameter fixation and biological stenting effect occurs.

[0163] The cytoskeletal inhibitor may be targeted, but is preferably administered directly to the traumatized vessel prior to, during or following the angioplasty or other traumatic event. The biological stenting effect of cytochalasin B, for example, is achievable using a single infusion of about 1 to about 24 ml, preferably about 5 to about 15 ml, of a vehicle plus the cytoskeletal inhibitor into the traumatized region of the vessel wall at a dose concentration ranging from about 0.1 microgram of therapeutic agent/ml of vehicle to about 10.0 micrograms of cytoskeletal inhibitor /ml of vehicle.

[0164] Inhibition of vascular smooth muscle cell migration (from the tunica media to the intima) has been demonstrated in the same dose range (Example 11); however, a sustained exposure of the vessel to the cytoskeletal inhibitor is preferable in order to maximize these anti-migratory effects. If the vascular smooth muscle cells cannot migrate into the intima, they cannot proliferate there. Should vascular smooth muscle cells migrate to the intima, a subsequently administered anti-proliferative sustained release dosage form can inhibit intimal proliferation. As a result, the sustained release dosage form embodiment of the present invention, incorporating a cytochalasin or other anti-proliferative cytoskeletal inhibitor, can be administered in combination with a free cytoskeletal inhibitor. In this manner, a biological stenting effect, as well as an anti-proliferative or anti-migratory effect, can be achieved in a single dosing protocol.

Method using Products of the Invention

[0165] The invention provides medicaments, compositions, kits and devices. These products may be used for treating a mammal having, or at risk of, diminution in vessel lumen volume, area or diameter, e.g., stenosis or restenosis of a blood vessel. The method comprises the administration of at least one cytoskeletal inhibitor in an amount effective to biologically stent a vessel, inhibit or reduce vascular remodeling of a vessel, inhibit or reduce vascular smooth muscle cell proliferation, or any combination thereof.

[0166] For the prevention of vessel lumen diminution associated with procedural vascular trauma, the cytoskeletal inhibitor can be administered before, during and/or after the procedure, or any combination thereof. For example, for the prevention of restenosis, a series of spaced doses of the cytoskeletal inhibitor, optionally, in sustained release dosage form, is preferably administered before, during and/or after the traumatic procedure (e.g., angioplasty). The dose may also be delivered locally, via an implantable device, e.g., a catheter, introduced into the afflicted vessel during the procedure. Preferably, a sustained release dosage form is administered via the implantable device during the traumatic procedure. After the traumatic procedure is conducted, a series of follow-up doses can be administered over time, preferably in a sustained release dosage form, for a time sufficient to substantially reduce the risk of, or to prevent, restenosis. A preferred therapeutic protocol duration for this purpose involves administration from about 3 to about 26 weeks after angioplasty.

[0167] It will be recognized by those skilled in the art that therapeutically/prophylactically effective dosages of the cytoskeletal inhibitors and dosage forms will be dependent on several factors, including, e.g.: a) the binding affinity of the vascular smooth muscle binding protein, if any, in the dosage form; b) the atmospheric pressure and duration of the pressure applied during infusion; c) the time over which the cytoskeletal inhibitor or dosage form administered resides at the vascular site; d) the nature of the cytoskeletal inhibitor employed; e) the nature of the vascular trauma and therapy desired; f) for sustained release dosage forms, the rate of release of the cytoskeletal inhibitor from the dosage form, and/or g) for sustained release dosage forms, the intercellular and/or intracellular localization of the dosage form. Those skilled practitioners trained to deliver drugs at therapeutically effective dosages (e.g., by monitoring drug levels and observing clinical effects in patients) will determine the optimal dosage for an individual patient based on experience and professional judgment. Those skilled in the art will recognize that infiltration of the cytoskeletal inhibitor into the intimal layers of a traumatized vessel wall in free or sustained release dosage form is subject to variation and will need to be determined on an individual basis.

[0168] A therapeutically effective dosage of the cytoskeletal inhibitor will be typically reached when the concentration of cytoskeletal inhibitor in the fluid space between the balloons of the catheter is in the range of about 10^{-3} to 10^{-12} M. It will be recognized from the Examples provided herewith that cytoskeletal inhibitors and dosage forms may only need to be delivered in an antiproliferative therapeutic dosage sufficient to expose the inner 10%, preferably the inner 20%, and more preferably the inner 99%, of the tunica media cells lining the lumen to the cytoskeletal inhibitor. This dosage can be determined empirically, e.g., by a) infusing vessels from suitable animal model systems and using immunohistochemical, fluorescent or electron microscopy methods to detect the agent and its effects (e.g., such as exemplified in the EXAMPLES below); and b) conducting suitable *in vitro* studies (see, for example, EXAMPLES 3, 4, and 5, below).

[0169] For example, with respect to catheter delivery, it will be recognized by those skilled in the art that therapeutically/prophylactically effective dosages of the cytoskeletal inhibitors and dosage forms will be dependent on factors including: a) the atmospheric pressure applied during infusion; b) the time over which the agent administered resides at the vascular site; c) the form of the cytoskeletal inhibitor employed; and/or d) the nature of the vascular trauma and therapy desired. Catheters which may be useful in the practice of the invention include catheters such as those disclosed in Just et al. (U.S. Patent No. 5,232,444), Abusio et al. (U.S. Patent No. 5,213,576), Shapland et al. (U.S. Patent No. 5,282,785), Racchini et al. (U.S. Patent No. 5,458,568), Wolinsky (U.S. Patent No. 4,824,436), Spears (U.S. Patent No. 4,512,762) and Shaffer et al. (U.S. Patent No. 5,049,132).

[0170] A therapeutically effective dosage is generally the pericellular agent dosage in smooth muscle cell tissue culture, i.e., a dosage at which at a continuous exposure results in a therapeutic effect between the toxic and minimal effective doses. This therapeutic level is obtained *in vivo* by determining the size, number and cytoskeletal inhibitor concentration and release rate required for particles infused between the smooth muscle cells of the artery wall to maintain this pericellular therapeutic dosage. The dosage form should release the cytoskeletal inhibitor at a rate that approximates the pericellular dose of the following exemplary therapeutic agents: from about 0.01 to about 100 micrograms/ml nitroglycerin, from about 1.0 to about 1000 micrograms/ml of suramin, from about 0.001 to about 100 micrograms/ml for cytochalasin, and from about 0.01 to about 105 nanograms/ml of staurosporin as well as from about 0.001 to about 100 micrograms/ml taxol. Thus, for cytochalasin B, the systemic dose results in about 5 to about 40, preferably about 8 to about 30, λ of the solution entering the interstitial space surrounding the cells of the tunica media, and about 0.01 to about 4, preferably about 0.05 to about 3, ml of the solution delivered to the wall of the vessel via the adventitia.

[0171] The administration of a cellular therapeutic dose of, for example, cytochalasin B to vascular smooth muscle

cells following balloon dilation trauma can be achieved by replacing the entire volume of the tunica media with the cytoskeletal inhibitor so as to produce a biostenting effect, i.e., all cells are exposed to a concentration of the cytoskeletal inhibitor effective to biologically stent the vessel. For example, a dose response study which employed swine femoral arteries showed that if the entire tunica media was infused using an infusion catheter with cytochalasin B in a range of about 0.1 µg/ml of vehicle to 10.0 µg/ml of vehicle, a biostenting effect resulted. That is, a more extensive retention of the artery lumen size (diameter or cross-sectional area) was observed relative to the artery lumen size produced by the dilating balloon. The therapeutic effect had a threshold level of 0.1 µg/ml cytochalasin B with no effect below this dose and no increase in therapeutic efficacy up to 10 µg/ml cytochalasin B. Thus, cytochalasin B has a wide therapeutic index which ranges from about 0.1 to about 10 µg/ml, with no evidence of toxicity at 10 µg/ml. Ten µg/ml is the maximum saturation concentration of cytochalasin B in saline. The therapeutic effect produced by cytochalasin B administration became more apparent over the 3 to 8 weeks following the balloon trauma.

[0172] To achieve a cellular therapeutic dose to produce a biostenting effect, i.e., one where each cell of the tunica media is exposed to a therapeutic concentration range, e.g., about 0.1 µg/ml to about 8.0 µg/ml of cytochalasin B, a catheter, e.g., a MIC2 or MIC3 catheter, is filled with a volume of the cytoskeletal inhibitor in solution and delivered at a hub pressure which does not damage the vessel. For example, 9 to 24 ml (MIC2) or 5 to 10 ml (MIC3) of an 8.0 µg/ml cytochalasin B solution is delivered at a hub pressure of 4 to 5 atmospheres for a total of 90 seconds infusion time. Delivery of the NR-ML-05 monoclonal antibody to the tunica media under these conditions was achieved in both the swine femoral and coronary models. With the hub pressure and exposure times held constant, the amount of solution infused may vary because flow rate is determined by the tightness of fit. If the flow rate is below the recommended range, the fit is too tight to establish a uniform hydrostatic head, and therefore a uniform dose around the vessel wall does not exist. If the flow rate is above the recommended range, then the fit is too loose to establish the hydrostatic head required to force the solution into the interstitial region of the tunica media, and the dose to the individual cells is below the required therapeutic level.

[0173] It is also preferred that catheter administration of the cytoskeletal inhibitor to the tunica media and adventitia produces minimal or no damage to the vessel wall by jetting or accentuating dissections produced by the PTCA procedure. Moreover, it is preferred that the hydrostatic head pressure at the interface of the infusion balloon and the vessel wall is between about 0.3 to about 1.5, preferably about 0.4 to about 0.8, and more preferably about 0.5 to about 0.75, atmospheres, so as to rapidly force the solution containing the cytoskeletal inhibitor into the tunica media interstitial space without rupturing the small vessels in the adventitia, the origin of which is exposed to the hydrostatic head.

[0174] Preferably, the administration of the cytoskeletal inhibitor results in uniform delivery of the cytoskeletal inhibitor to the tunica media. Moreover, the catheter administration of the cytoskeletal inhibitor results in the delivery of an effective amount of the agent to the adventitia via the vasa vasorum, as well as the tunica media. Preferably, the cytoskeletal inhibitor is also uniformly distributed to the adventitia. Catheter administration of a cytoskeletal inhibitor, e.g., about 4 to about 24 ml of cytochalasin B at about 8.0 µg/ml, preferably results in a uniform pattern of cytoskeletal inhibitor delivery, at a depth of penetration to at least about the inner 10%, more preferably to at least about the inner 20%, even more preferably to the inner 100%, of the tunica media. By the time a cytoskeletal inhibitor diffused from the inner 10% of the tunica media to its outer limits in a swine coronary study, it was found that the cells at the outer limits were exposed to a therapeutic dose.

[0175] A preferred form of the cytoskeletal inhibitor includes cytochalasin B in sterile saline at a concentration of about 8.0 µg/ml, in 30 ml vials, which should deliver the preferred cellular therapeutic dose described hereinabove needed to treat a single lesion. Preferably, the amount is uniformly distributed to the inner 20% of the tunica media and uniformly distributed to the adventitia.

[0176] In another therapeutic method, a solution of a cytoskeletal inhibitor is infused, *in vivo* or *ex vivo*, into the walls of isolated vessels (arteries or veins) to be used for vascular grafts. In this example, the vessel that is to serve as the graft is excised or isolated and subsequently distended by an infusion of a solution of a cytoskeletal inhibitor. Preferably the infusion is accomplished by a hub pressure of about 4 to about 5 atm for a time period of from about 1 to about 4 minutes, preferably for about 1 to about 2 minutes. This infusion regime will result in the penetration of an efficacious dose of the cytoskeletal inhibitor to the smooth muscle cells of the vessel wall. Preferably, the cytoskeletal inhibitor will be at a concentration of from about 0.1 µg/ml to about 8.0 µg/ml of infusate. Preferably, the cytoskeletal inhibitor will be a cytochalasin, and most preferably, the cytoskeletal inhibitor employed will be cytochalasin B, or a functionally equivalent analogue thereof.

[0177] It is known to those of ordinary skill in the art that peripheral vessels that are used for vascular grafts in other peripheral sites or in coronary artery bypass grafts, frequently fail due to post surgical stenosis. Since cytochalasin B infusion maintains the vascular luminal area in surgically traumatized vessels by virtue of its biological stenting activity, its administration in this process can retard the ability of the vessel to contract, resulting in a larger luminal diameter or cross-sectional area. Furthermore, it is an advantage of this embodiment that the administration of cytochalasin B in this manner can prevent the constriction or spasm that frequently occurs after vascular grafts are anastomosed to both their proximal and distal locations, that can lead to impaired function, if not total failure, of vascular grafts. Thus,

the vessel stenting produced by cytochalasins should decrease the incidence of spasms, which can occur from a few days to several months following the graft procedure.

[0178] In another use the products of the invention may be used in situations in which angioplasty is not sufficient to open a blocked artery, such as those situations which require the insertion of an intravascular stent or shunt or other implantable devices. Thus, the invention also provides stents, adventitial wraps, synthetic grafts or shunts comprising the cytoskeletal inhibitor in solid form. A preferred cytoskeletal inhibitor is a cytochalasin, for example, cytochalasin B or an analog thereof which is a functional equivalent of cytochalasin B. Another preferred cytoskeletal inhibitor of the invention is taxol or an analog of taxol which is a functional equivalent of taxol. Preferably, the cytoskeletal inhibitor is in sustained release dosage form.

[0179] Thus, an implantable device, e.g., an intravascular stent or shunt, provides a mechanical means of providing an increase in luminal diameter of a vessel, in addition to that provided via the biological stenting action and/or anti-proliferative activity of the cytoskeletal inhibitor, such as cytochalasin B or taxol, releasably embedded therein or administered in solution or suspension during the interventional procedure. Furthermore, the placement of an implantable device comprising a cytoskeletal inhibitor which is an inhibitor of smooth muscle cell proliferation provides an increased efficacy by reducing or preventing intimal proliferation. This inhibition of intimal smooth muscle cells and stroma produced by the smooth muscle allows for more rapid and complete re-endothelization following the intravascular placement of the device.

Kits Comprising an Implantable Delivery Device and At Least One Cytoskeletal Inhibitor of the Invention

[0180] The invention provides a kit comprising packing material enclosing, separately packaged, at least one implantable device adapted for the delivery of a cytoskeletal inhibitor, e.g., a catheter, an adventitial wrap, a valve, a stent, a shunt or a synthetic graft, and at least one unit dosage form comprising a cytoskeletal inhibitor, as well as instruction means for their use, in accord with the present methods. The unit dosage form may comprise an amount of at least one of the present cytoskeletal inhibitors effective to accomplish the therapeutic results described herein when delivered locally and/or systemically. A preferred embodiment of the invention is a kit comprising a catheter adapted for the local delivery of at least one cytoskeletal inhibitor to a site in the lumen of a mammalian vessel, along with instruction means directing its use in accord with the present invention. In a preferred aspect, the infusion catheter may be conveniently a double balloon or quadruple balloon catheter with a permeable membrane.

[0181] It is also envisioned that the kit of the invention comprises a non-catheter delivery device, e.g., an adventitial wrap, a valve, stent or shunt, for systemic or local delivery. A valve, stent, wrap or shunt useful in the methods of the invention can comprise a biodegradable coating or porous non-biodegradable coating, e.g., a PTFE membrane, having dispersed therein one or more cytoskeletal inhibitors as described herein, preferably a sustained release dosage form of the cytoskeletal inhibitor.

[0182] Another embodiment of the invention is a kit comprising a device adapted for the local delivery of at least two cytoskeletal inhibitors, a unit dosage of a first cytoskeletal inhibitor, and a unit dosage of a second cytoskeletal inhibitor, along with instruction means directing their use in accord with the present invention. The unit dosage forms of the first and second cytoskeletal inhibitors may be introduced via discrete lumens of a catheter, or mixed together prior to introduction into a single lumen of a catheter. If the unit dosage forms are introduced into discrete lumens of a catheter, the delivery of the cytoskeletal inhibitors to the vessel can occur simultaneously or sequentially. Moreover, a single lumen catheter may be employed to deliver a unit dosage form of one cytoskeletal inhibitor, followed by the reloading of the lumen with another cytoskeletal inhibitor and delivery of the other cytoskeletal inhibitor to the lumen of the vessel. Either or both unit dosages can act to reduce the diminution in vessel lumen diameter at the target site.

[0183] Alternatively, a unit dosage of one of the cytoskeletal inhibitors may be administered locally, e.g., via catheter, while a unit dosage of another cytoskeletal inhibitor is administered systemically, e.g., via oral administration.

[0184] The invention will be better understood by making reference to the following specific examples.

EXAMPLE 1

Binding to Vascular Smooth Muscle Cells In the Blood Vessel Wall *In Vivo*

[0185] FIGURE 1B illustrates the binding of NR-AN-01 (a murine IgG2b MAb) to the smooth muscle cells in the vascular wall of an artery in a 24-year old male patient, 4 days after the i.v. administration of NR-AN-01. FIGURE 1B is a photomicrograph of a histological section taken through the medial region of an arterial wall of the patient after NR-AN-01 administration, where the section was reacted ex vivo with HRP-conjugated goat anti-mouse IgG. The reaction of the HRP-conjugate with NR-AN-01 MAb was visualized by adding 4-chloro-1-naphthol or 3,3'-diaminobenzidine tetrahydrochloride as a peroxidase substrate (chromogen). The reaction product of the substrate forms an insoluble purple or dark brown precipitate at the reaction site (shown at #2, FIGURE 1B). A counter stain was used to

visualize collagenous extracellular matrix material (shown at #2, FIGURE 1B). Smooth muscle cells are visualized under microscopic examination as purple stained cells (FIGURE 1a and FIGURE 1B). This photomicrograph (FIGURE 1B) demonstrates the ability of the MAb to specifically bind to human vascular smooth muscle *in vivo*, and to be internalized by the cells and remain in the cells for extended periods.

EXAMPLE 2

Therapeutic Conjugates Containing Trichothecene

[0186] Conjugates of NR-AN-01 and Roridin A were constructed by chemically coupling a hemisuccinate derivative of the trichothecene cytotoxin (as described below) to a monoclonal antibody designated NR-AN-01. Two conjugates were prepared, one coupled at the Roridin A 2' position and one at the 13' position. Two schemes were used in this synthesis, as depicted in FIGURE 2 and FIGURE 3. The conjugate was then purified from unreacted Roridin A by PD-10 SEPHAROSE® column chromatography (Pharmacia; Piscataway, NJ), analyzed by size exclusion high pressure liquid chromatography, and the column fractions were characterized by SDS-PAGE and isoelectric focusing (IEF), as described below.

[0187] FIGURE 2 shows diagrammatically the first reaction scheme for synthesis of Roridin A hemisuccinyl succinimide (RA-HS-NHS) through a two step process with reagents: succinic anhydride, triethylamine (NEt_3) and dimethyl amino pyridine (DMAP) present in dichloromethane (CH_2Cl_2) at room temperature (RT); and, N-hydroxysuccinimide (NHS) and dicyclohexyl carbodiimide (DCC) reagents also in CH_2Cl_2 at RT.

[0188] FIGURE 3 shows diagrammatically the second reaction scheme for synthesis of Roridin A hemisuccinyl succinimide (RA-HS-NHS) through a five step process with reagents: t-butyl dimethyl silyl chloride (TBMS-Cl) and imidazole in dimethylformamide (DMF) at room temperature (RT); acetic anhydride, triethylamine (TEA), and diethylaminopyridine in dichloromethane (CH_2Cl_2) at RT; succinic anhydride, triethylamine (TEA) and dimethylaminopyridine (DMAP) in (CH_2Cl_2) at RT; and, N-hydroxysuccinimide (NHS) and dicyclohexyl carbodiimide (DCC) reagents.

Synthesis of 2' Roridin-A Hemisuccinic Acid (2):

[0189] To 0.5 g (0.94 mmol) of Roridin A, 15 ml of dichloromethane was added. To this solution with stirring was added 0.104 g (1.04 mmol) of succinic anhydride. To the reaction mixture, 0.2 ml of triethylamine in 5 ml dichloromethane was added. To the homogeneous reaction mixture, a catalytic amount of dimethylaminopyridine was added and stirred at room temperature for 15 hours. Completion of the reaction was followed by thin layer chromatography ($\text{CH}_2\text{Cl}_2 : \text{CH}_3\text{OH} = 9.7 : 0.3$ with few drops of acetic acid). At the end of the reaction, 0.3 ml of glacial acetic acid was added and the solvent removed under reduced pressure. The dried crude residue was partitioned between water and methylene chloride. The combined methylene chloride extracts (3 x 50 ml) were dried over anhydrous sodium sulfate, solvent was removed under vacuum and dried to yield 0.575 g (96%) of a crude mixture of three compounds. Preparative C18 HPLC separation of the crude mixture in 50% acetonitrile-water with 2% acetic acid yielded 0.36 g (60%) of 2 as a white solid.

Synthesis of Succinimidyl 2' - Roridin A Hemisuccinate (3):

[0190] To 0.3 g (0.476 mmol) of 2' Roridin A hemisuccinic acid in 30 ml dichloromethane, 0.055 g (0.478 mmol) N-hydroxysuccinimide was added. To the clear reaction mixture, 0.108 g (0.524 mmol) dicyclohexylcarbodiimide was added. The reaction mixture was stirred at room temperature for 6 hours. Completion of the reaction was followed by TLC ($\text{CH}_2\text{Cl}_2 : \text{CH}_3\text{OH} = 9.7 : 0.3$ with a few drops of acetic acid) as a developing solvent. A few drops of glacial acetic acid was added to the reaction mixture and the solvent was removed under reduced pressure. To the dried residue dichloromethane was added and the precipitated DCU was filtered. Solvent from the filtrate was removed under reduced pressure to yield a white solid. From the crude product, 0.208 g (60%) of 3 was purified by preparative HPLC in 50% acetonitrile with 2% acetic acid as a mobile phase.

Synthesis of 13'-t-Butyldimethylsilyl Roridin A (4):

[0191] To 72.3 mg (0.136 mmol) of Roridin A in 0.5 ml dimethylformamide solution, 0.055 g (0.367 mmol) t-butyldimethylsilyl chloride and 0.025 g (0.368 mmol) of imidazole were added. The reaction mixture was stirred at room temperature for 15 hours. Completion of the reaction was followed by silica gel thin layer chromatography using 1% MeOH- CHCl_3 as a developing solvent. Solvent from the reaction mixture was removed in vacuo and dried. The crude product was partitioned between water and methylene chloride. Solvent from the combined methylene chloride extracts was removed under reduced pressure and dried. The crude product was purified by flash chromatography using EtOAc :

Hexane (1:3) as an eluting solvent. Solvent from the eluants was removed under reduced pressure to yield 0.66 g (75%) of 4 as a solid.

Synthesis of 13'-t-Butyldimethylsilyl 2' Acetyl Roridin A (5):

[0192] To 0.1 g (0.155 mmol) of 13'-t-butyldimethylsilyl Roridin A in 10 ml dichloromethane, 0.3 ml acetic anhydride, 0.2 ml triethylamine and a few crystals of dimethylaminopyridine were added and stored at room temperature for 2 hours. Completion of the reaction was followed by TLC in 1% methanol-methylene chloride as a developing solvent. Solvent was removed under reduced pressure and purified by a silica gel column using 1% methanol-chloroform as an elution solvent. Solvent from the eluants was removed under vacuum to yield 0.085 g (80%) of 5 as a solid.

Synthesis of 2' Acetyl Roridin A (6):

[0193] To 0.05 g (0.073 mmol) of 2' acetyl 13'-t-butyldimethylsilyl Roridin A in 5 ml tetrahydrofuran, 0.3 ml of 1 M tetrabutyl-ammonium fluoride solution in THF was added. The reaction mixture was stirred at room temperature for 2 hours. Completion of the reaction was followed by silica gel thin layer chromatography using 1% MeOH-CHCl₃ as the developing solvent. Solvent from the reaction mixture was removed under reduced pressure and dried. The crude product was purified on a silica gel column using 1% CH₃OH - CHCl₃ as an eluting solvent. Solvent from the combined eluants were removed under vacuum to yield 0.020 g (48%) of 6 as a solid.

Synthesis of 2'-Acetyl 13'-hemisuccinyl Roridin A (7):

[0194] To 0.05 g (0.087 mmol) of 2'-acetyl Roridin A in 1 ml of dichloromethane, 0.025 g (0.25 mmol) succinic anhydride and 35 ml of triethylamine was added. A few crystals of dimethylaminopyridine was added as a catalyst. The reaction mixture was stirred at room temperature for 24 hours. Completion of the reaction was followed by thin layer chromatography using 5% MeOH-CH₂Cl₂ as developing solvent. At the end of the reaction 30 ml of glacial acetic acid was added. Solvent from the reaction mixture was removed under reduced pressure and dried. The crude product was partitioned between water and ethyl acetate. Solvent from the combined ethyl acetate fractions was removed under reduced pressure. Crude product was purified by passing through a silica gel column to yield 0.039 g (66%) of 7 as a white solid.

Synthesis of Succinimidyl 2'-Acetyl 13' - Roridin A Hemisuccinate (8):

[0195] To 0.036 g (0.0050 mmol) of 2'-acetyl 13'-Roridin A hemisuccinic acid in 2 ml dichloromethane, 0.009 g (0.09 mmol) N-hydroxysuccinimide was added. To a stirred solution, 0.012 g (0.059 mmol) dicyclohexylcarbodiimide was added. The reaction mixture was stirred at room temperature for 8 hours. Completion of the reaction was followed by silica gel thin layer chromatography using 5% MeOH-CH₂Cl₂ as a developing solvent. A few drops of glacial acetic acid was added to the reaction mixture. Solvent from the reaction mixture was removed under reduced pressure and dried. The crude product was purified on a silica gel column using 5% MeOH-CH₂Cl₂ as an eluting solvent. Solvent from the combined eluants was removed under vacuum to yield 0.025 g (61%) of 8 as a white solid.

Conjugation of Succinimidyl 2'-Roridin A Hemisuccinate (3) and Succinimidyl 2'-Acetyl 13'-Roridin A Hemisuccinate (8) to NR-AN-01 Whole Antibody (MAb):

[0196] Conjugation reactions were performed at pH 8.0 in borate buffer in the presence of 25% dimethylsulfoxide (DMSO) solvent at room temperature with gentle mixing for 45 minutes prior to purification by gel permeation chromatography. The molar trichothecene drug precursor to antibody offerings were 25:1 and 40:1 for the 2' and 13' Roridin A analogues (3 and 8), respectively. Antibody concentration was 0.9 to 1.0 mg/ml during the conjugation reaction.

A Typical 2' Analogue (3) Reaction with 25 mg of Antibody was as follows:

[0197] To 4.7 ml of 5.3 mg Ab/ml in phosphate buffered saline (i.e., PBS; 150 mM NaCl, 6.7 mM Phosphate, pH 7.3) was added 10 ml PBS and 5 ml of borate buffer (0.5 M, pH 8.0). With stirring gently to the reaction mixture, 6.3 ml of DMSO containing 1.37 mg of succinimidyl 2' Roridin A hemisuccinate (3) was then added dropwise over a 15 second period.

Purification:

[0198] To purify, one ml reaction aliquots were applied to Pharmacia PD-10 Sepharose® columns equilibrated in PBS. The eluted conjugate was collected in 2.4 to 4.8 ml fractions. The PD-10 purified conjugate aliquots were then pooled and concentrated on an Amicon PM-10 DiAflo® concentrator to 1.5 to 2.0 mg of Ab/ml; sterile filtered through a 0.2 Gelman Acrodisc® and filled into sterile glass vials in 5 ml volume.

[0199] The 2' conjugate was quick frozen in liquid nitrogen and then stored at -70°C until use. The 13' Roridin A NR-AN-01 conjugate was stored frozen or refrigerated (i.e., 5-10°C).

Characterization of Conjugates:

[0200] Protein concentration was determined by BCA assay using the copper reagent method (Pierce Chemical Corp.).

[0201] Assessment of degree of antibody derivatization was performed by first hydrolyzing an aliquot of conjugate in 0.2 M carbonate, pH 10.3 for 4 hours (at room temperature for 2' conjugate or at 37°C for the 13' conjugate) followed by filtration through a PM-30 membrane. The filtrate was then assayed for Roridin A on C-18 reverse phase HPLC using a mobile phase of 50:48:2 ratio CH₃CN:H₂O:HOAC, respectively. A 1.32 correction factor was used to correct for parallel macrocyclic ring decomposition that gives polar products during the hydrolysis of the 13' conjugate.

[0202] Size exclusion chromatography on DuPont Zorbax® HPLC and isoelectric focusing using Serva® gel plates (pH 3 to 10) were also performed. No indication of aggregation was observed by HPLC.

[0203] Immunoassay of the Roridin A-antibody conjugates was performed by either competitive ELISA using biotinylated-Ab with Streptavidin/Peroxidase detection or by a competitive cell binding assay using ¹²⁵I-labeled antibody. Alternatively, immunoreactivity was measured under conditions of antigen saturation in a cell binding assay wherein antibody was first trace labeled with 1-125 by the chloramine T method and then subsequently derivatized with 2' and 13' Roridin A precursors.

EXAMPLE 3

Kinetics of Binding to Smooth Muscle Cells

[0204] For administration by i.v. catheter, it is desirable that the therapeutic conjugates be administered in less than 3 to 5 minutes, so that blood flow can be reestablished in the patient. Therefore, studies were conducted to determine the binding kinetics of a smooth muscle binding protein with a K_a of >10⁹ liter/mole. Because human vascular smooth muscle cells grow slowly in culture, and baboon smooth muscle cells were found to express the human CSPG cell surface marker, BO54 baboon artery smooth muscle cells and human A375 M/M (melanoma; ATCC #CRL1619) cells bearing CSPG surface marker were used in many of the studies described in the Examples, below.

[0205] For the kinetic binding studies, A375 M/M and BO54 cells were seeded in sterile 96 well microtiter plates at 2500 cells/well. Plates were wrapped in aluminum foil, and incubated at 37°C overnight in a humidified atmosphere of 5% CO₂/95% air. After approximately 18 hr, incubation plates were removed and cells were fixed with 0.05% glutaraldehyde for 5 minutes to prevent membrane turnover. Following fixation, the plates were exhaustively washed with PBS containing 0.5% Tween-20®. Serial two-fold dilutions of an NR-AN-01 therapeutic conjugate containing Roridin A were prepared at protein concentrations of 10 mg/ml to 20 ng/ml, and each dilution was aliquoted into two wells. The plates were incubated at 4 ° C with the NR-AN-01 for 5, 15, 30, and 60 minutes, after which the unbound protein was removed by aspiration and 100 ml of CS buffer was added (5% chicken serum/ 0.5% Tween-20® in PBS) to each well. CS buffer was removed and the NR-AN-01 therapeutic conjugate bound to the cells was visualized by adding 100 ml of HRP-conjugated goat anti-mouse IgG (Sigma Chemical Co., St. Louis, MO) to each well; incubating at 4°C for 1 hr.; washing with PBS/0.05% Tween® to remove unbound goat IgG; and, adding 2,2'-azino-bis(3-ethylbenzthiazoline-6-sulfonic acid (ABTS) chromogenic substrate (i.e., for HRP). After incubating for 30 minutes, the amount of NR-AN-01 bound to the cells was quantified by measuring the absorbance at 415 nm and 490 nm using an ELISA plate reader equipped for data acquisition by a Compaq computer.

[0206] FIGURE 4A graphically depicts the results of *in vitro* studies in which A375m/m marker-positive cells were held at 4°C (i.e., to prevent membrane turnover) for 5 minutes (open squares, FIGURE 4A), 15 minutes (closed diamonds, FIGURE 4A), 30 minutes (closed squares, FIGURE 4A) or 60 minutes (open diamonds, FIGURE 4A) with different concentrations of NR-AN-01 (NRAN01 µg/ml). The binding of the NR-AN-01 MAb to the A375 cells was quantified by washing to remove unbound antibody, adding HRP-conjugated goat anti-mouse IgG to react with the cell-bound MAb, washing to remove unbound goat second antibody, and adding 2,2'-azino-bis(3-ethylbenzthiazoline-6-sulfonic acid) (ABTS) substrate for peroxidase. Color development was monitored after 30 minutes at both 415 nm and 490 nm (ABS415,490).

[0207] FIGURE 4B graphically depicts the results of *in vitro* studies conducted in a manner similar to those described above in regard to FIGURE 4A, but using BO54 marker-positive smooth muscle cells, i.e., instead of the A375 m/m cells.

[0208] The results presented in FIGURE 4A and FIGURE 4B show significant binding of NR-AN-01 to A375 and BO54 cells within 5 minutes at 4°C, even at the lowest dose of 20 ng/ml.

EXAMPLE 4

Effects of Roridin A and RA-NR-AN-01 Conjugates

[0209] The effects of Roridin A (RA) and RA-NR-AN-01 conjugates on cellular protein synthesis (i.e., by ³H-leucine incorporation) and metabolic activity (i.e., by mitochondrial MTT assay) were tested in the experiments detailed in EXAMPLE 5 and EXAMPLE 6, below. The studies in EXAMPLE 4 include experiments to determine the effects of long-term (i.e., 24 hour) treatment with the agents. The studies in EXAMPLE 5 include experiments to determine the effects of "pulse" (i.e., 5 minute) treatment on cells. In both studies, the cellular specificity of the effects were evaluated by including "target" cells (i.e., cells bearing the CSPG "marker") and non-target cells. For comparative purposes, free-RA (i.e., uncoupled) was also included in the studies. The effects on cellular protein synthesis or metabolic activity were evaluated either immediately following the treatment, or a "recovery period" was allowed (i.e., involving incubation of the cells overnight at 37°C) to determine the long-term effects of the agents on the cell populations.

Metabolic Effects After 24 Hours Exposure:

[0210] While it is known that monoclonal antibody-drug conjugates may have a degree of specificity for cells bearing marker antigens when employed *in vivo*, it has proven more difficult in many systems to demonstrate *in vitro* specificity of action, especially with compounds that are lipophilic. Therefore, the present experiments were conducted in which the inhibitory effects of the NR-AN-01-Roridin A conjugate was tested on target and non-target cells over 24 hours. The results with RA-NR-AN-01 were compared to the effect of free Roridin A over the same 24-hour period. A modified methyl-tetrazolium blue (MTT) assay was utilized with 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (Sigma) to determine cellular metabolic activity. This assay is thought to measure cellular mitochondrial dehydrogenase activity. For some of these studies, M14 (melanoma) and BO54 (smooth muscle) cell lines were used as marker-positive target cells and HT29 cells (colon carcinoma; ATCC #HTB38) were used as the non-target specificity control. In other studies, A375 was used as a marker-positive cell. The HT29 and M14 cells were seeded in 96-well microtiter plates at a concentration of 5.0×10^3 cells/well, and the BO54 cells were seeded at 2.5×10^3 cells/well. Serial two-fold dilutions of free Roridin A and 2'RA-HS-NR-AN-01 (i.e., Roridin A coupled through a hemisuccinate (HS) coupling agent at the 2' position to NR-AN-01) were prepared in DMEM over a range of protein concentrations from 20 mg/ml to 40 pg/ml. Test agents were added (in duplicate) to microtiter wells (100 ml/well), and the plates were wrapped in aluminum foil and incubated at 37°C in a humidified atmosphere consisting of 5% CO₂/95% air for 24 hours. After 24 hours, medium was removed (by aspiration), fresh DMEM was added (100 ml/well), and the cells were returned to incubate for an additional overnight (i.e., 16-18 hours) "recovery period". At the end of the "recovery period" cellular metabolic activity was determined by adding 20 ml to each well of a 5 mg/ml MTT solution. The plates were covered and incubated at 37°C for 4 hours and then the reaction was developed by adding 100 ml/well of 10% SDS/0.1 N HCl. The dark blue solubilized formazan reaction product was developed at room temperature after 16-18 hours and quantified using an ELISA microtiter plate reader at an absorbance of 570 nm.

[0211] FIGURE 5A graphically depicts the results of *in vitro* studies in which BO54 marker-positive smooth muscle cells were incubated with different concentrations of RA-NR-AN-01 (NRAN01-RA; open squares, FIGURE 5A) or free Roridin A (Free RA; closed diamonds, FIGURE 5A) for a period of 24 hours, washed, and then returned to culture for an additional 16-18 hour overnight (o/n) recovery period prior to testing metabolic activity in an MTT assay. The concentrations of Free RA and RA-NR-AN-01 are expressed as the calculated concentration of Roridin A (in mg/ml plotted on a log scale) in the assay (i.e., rather than the total mg/ml of NR-AN-01 protein in the assay), so that direct comparisons could be made. The metabolic activity of the cells in the MTT assay is presented as the percentage of the metabolic activity measured in a control untreated culture of cells (i.e., % control).

[0212] FIGURE 5B graphically depicts the results of *in vitro* studies conducted in a manner similar to those described above in regard to FIGURE 5A, but comparing the effects of only RA-NR-AN-01 (NRAN01-RA) on three different cell types: namely, BO54 marker-positive smooth muscle cells (BO54-NRAN01-RA; open squares, FIGURE 5B); HT29 marker-negative control cells (HT29-NRAN01-RA; closed diamonds, FIGURE 5B); and, M14 marker-positive cells (M14-NRAN01-RA; closed squares, FIGURE 5B). As described above in regard to FIGURE 5A, the concentrations in the present experiment are expressed in terms of ug/ml of Roridin A. Metabolic activity of the cells is expressed in a manner similar to that in FIGURE 5A, i.e., as the percentage of activity measured in an untreated control culture of cells (% control).

[0213] The results presented in FIGURE 5A and FIGURE 5B show that metabolic activity measured in the MTT assay was significantly decreased in all populations of test cells, even 16-18 hours after a 24-hour incubation in either free Roridin A or the 2' or 13' RA-NR-AN-01 conjugates. The effects of the RA-NR-AN-01-conjugates appeared to be non-specifically inhibitory for both target (BO54 and M14) and non-target (HT29) cells (FIGURES 5A and 5B). The inhibitory effects were observed at a free Roridin A or RA-conjugate concentration of >10 ng/ml.

[0214] For comparative purposes, a second study was conducted in which the effects of *Pseudomonas* exotoxin (PE) conjugates on cells were evaluated in a similar protocol. For these studies, target and non-target cells were treated with PE or PE-NR-AN-01 for 24 hours, and then allowed a "recovery period" (as above) before metabolic activity was tested in an MTT assay.

[0215] FIGURE 6A graphically depicts the results of *in vitro* studies conducted in a manner similar to those described above in regard to FIGURE 5A, but designed to study the metabolic effects of PE-NR-AN-01 (NRAN01-PE) on cells, i.e., rather than RA-NR-AN-01. Three different cell types were utilized: namely, BO54 marker-positive smooth muscle cells (BO54; open squares, FIGURE 6A); HT29 marker-negative control cells (HT29; closed diamonds, FIGURE 6A); and, M14 marker-positive cells (MT14; closed squares, FIGURE 6A). In this study, the concentration of conjugate is expressed in µg/ml NR-AN-01 protein (plotted on a log scale), and the metabolic activity is expressed as the percentage of the MTT activity measured in an untreated control culture (% control).

[0216] FIGURE 6B graphically depicts the results of *in vitro* studies conducted in manner similar to those discussed above in regard to FIGURE 6A, but designed to compare the effects obtained with free PE (PE) to those obtained above, i.e., in FIGURE 6A, with PE-NR-AN-01. The cells, culture conditions, calculations, and presentation of the results are the same as in FIGURE 6A, above.

[0217] The results presented in FIGURE 6A and FIGURE 6B show that 24 hours exposure to PE-NR-AN-01 or free PE was non-specifically inhibitory to cells at concentrations of >100 ng/ml.

[0218] While this type of non-specific inhibition was judged to be of potential value for biological atheroectomy, it was not considered desirable for treatment of restenosis following angioplasty where dead and dying cells may release factors that stimulate smooth muscle proliferation.

EXAMPLE 5

Effects of Pulse-Treatment on Cellular Activity

[0219] Additional studies were conducted to evaluate the effects of a short-term, i.e., 5 minute, exposure to a Roridin A-containing therapeutic conjugate on cells. In these studies, both metabolic activity (measured in MTT assays) and cellular protein synthesis (measured by ³H-leucine incorporation) were evaluated.

Effects After 5 Minutes of Exposure: Protein Synthesis

[0220] The effects of a 5-minute exposure to free Roridin A (RA) or a therapeutic conjugate were evaluated. Roridin A-NR-AN-01 coupled through a hemisuccinyl (HS) at either the 2' position (2'RA-HS-NR-AN-01) or the 13' position (13'RA-HS-NR-AN-01) were employed. (In the case of 13'RA-HS-NR-AN-01, the 2' position of Roridin A was also acetylated.) The RA, 2' or 13'RA-NR-AN-01 conjugates were diluted two fold in sterile DMEM over a range of concentrations from 400 ng/ml to 780 pg/ml of Roridin A. (The test samples were all normalized to Roridin A, so that direct comparisons could be made of the effects at comparable doses.) Samples were aliquoted (in duplicate) into duplicate microtiter plates at 100 µl/well and incubated at room temperature for five minutes.

[0221] Both short-term and long-term effects of the test samples on marker-positive A375 and marker-negative HT29 cells were determined. For studying the short-term effects, 100 µl/well of [³H]-leucine (0.5 mCi/ml) was added immediately after the 5-minute treatment with conjugate (or RA) and protein synthesis was evaluated over a four-hour period. For determining the long-term effects, the cells were treated for 5 minutes, washed, and then returned to culture for a 24-hour "recovery" period in DMEM medium containing either 5% NBS/5% Serum Plus® (i.e., for A375 or HT29 cells) or 10% FBS (i.e., for BO54 cells). At the end of the "recovery" period, the incubation medium was removed (i.e., by aspiration) and ³H-leucine was added (as above). In both cases (i.e., whether short-term or long-term), protein synthesis of the cells was evaluated by incubating the cells with the ³H-leucine for 4 hours at 37°C in a humidified chamber (as above), and all results are calculated by comparison with non-treated cells (i.e., 100% control). After 4 hours the ³H-leucine was removed, the cells were removed from the substrata by trypsin-treatment, aspirated (using a PHD™ cell harvester (Cambridge Technology, Inc., Cambridge, MA)) and collected by filtration on glass fiber filters. The glass fiber filters were dried and radioactivity quantified by liquid scintillation spectroscopy in a Beckman liquid scintillation counter.

[0222] FIGURE 7A graphically depicts the results of *in vitro* studies conducted to investigate the effects on control HT29 marker-negative cells of a 5 minute exposure to different concentrations of Roridin A (Free RA; open squares,

FIGURE 7A), or 2'RA-NR-AN-01 (2'RA-NRAN01; closed squares, FIGURE 7A), or 13'RA-NR-AN-01 (13'RA-NRAN01; closed triangles, FIGURE 7A) conjugates. The concentrations of Free RA, 2'RA-NR-AN-01 or 13'NR-AN-01 are expressed as the calculated concentration of Roridin A in the assay (in $\mu\text{g/ml}$ plotted on a log scale), i.e., rather than the total $\mu\text{g/ml}$ of NR-AN-01 protein, so that direct comparisons of the results can be made. For these studies, the cells were treated for 5 minutes, washed, and then returned to culture for 4 hours, during which time cellular protein synthesis was evaluated by adding 0.5 mCi/ml of ^3H -leucine to the culture medium. At the end of the 4 hour period, cellular proteins were collected and radioactivity was determined. The results are expressed as the percentage of the radioactivity recorded in a control (non-treated) HT29 cell culture (i.e., %control).

[0223] FIGURE 7B graphically depicts the results of *in vitro* studies investigating the effects on control HT29 marker-negative cells of a 5 minute expose to different concentrations of Free RA (open squares, FIGURE 7B), 2'RA-NRAN01 (closed squares, FIGURE 7B), or 13'RA-NRAN01 (closed triangles, FIGURE 7B), as described above in regard to FIGURE 7A, but in the present experiments the cells were incubated for a 16-18 hour recovery period (i.e., overnight; o/n) prior to testing protein synthesis in a four hour ^3H -leucine protein synthesis assay. The results are presented in a manner similar to those above in FIGURE 7A.

[0224] The results presented in FIGURE 7A and FIGURE 7B show the short-term and long-term effects, respectively, of RA, 2'RA-HS-NR-AN-01, and 13'RA-HS-NR-AN-01 on protein synthesis by HT29 control cells. The results show a dose-response inhibition of cellular protein synthesis by the free Roridin A, but not by RA-NR-AN-01, in HT29 cells. The inhibition triggered by RA during the 5 minutes of incubation was still manifest after the 16-18 hours recovery period (FIGURE 7B). In contrast, treatment of non-target HT29 cells with 2'RA-HS-NR-AN-01 or 13'RA-HS-NR-AN-01 did not result in detectable inhibition of protein synthesis. Thus, these results (in contrast to those obtained above over 24 hours) seem to suggest a surprising degree of specificity to the *in vitro* action of the NR-AN-01-conjugates when treatment was delivered in a 5-minute "pulse". However, it was also possible that the NR-AN-01-conjugate was inactive, and so additional experiments were conducted to evaluate the effect of the conjugates on target cells.

[0225] FIGURE 7C graphically depicts the results of *in vitro* studies investigating the effects on A375m/m marker-positive cells of a 5 minute exposure to different concentrations of Free RA (open squares, FIGURE 7C), 2'RA-NR-AN-01 (closed squares, FIGURE 7C) or 13'RA-NR-AN-01 (closed triangles, FIGURE 7C), as described above in regard to FIGURE 7A. In the present studies, the A375 cells were incubated for 5 minutes in the test agent, washed, and tested for protein synthesis over the next 4 hours by adding 0.5 mCi/ml ^3H -leucine to the culture medium. The results of the experiments are plotted in a manner similar to those described, above, in regard to FIGURE 7A.

[0226] FIGURE 7D graphically depicts the results of *in vitro* studies investigating the effects on A375 m/ml marker-positive cells of a 5 minute exposure to different concentrations of Free RA (open squares, FIGURE 7D), 2'RA-NRAN01 (closed squares, FIGURE 7D), 13'RA-NRAN01 (closed triangles, FIGURE 7D), as described above in regard to FIGURE 7B. In the present studies, the A375 cells were incubated for 5 minutes in the test agent, washed, and then returned to culture for a 16-18 hour recovery period (i.e., overnight; o/n Recovery), after which time protein synthesis was evaluated during a 4 hour ^3H -leucine protein synthesis assay. The results of the experiments are plotted in a manner similar to those described above in regard to FIGURE 7A.

[0227] The results presented in FIGURES 7C and FIGURE 7D show the short-term and long-term effects, respectively, of RA, 2'RA-HS-NR-AN-01 and 13'RA-HS-NR-AN-01 on protein synthesis by A375 target cells. Treatment of target cells with either the 2' or 13'RA-NR-AN-01 therapeutic conjugate resulted in a short-term inhibition of protein synthesis, i.e., observed immediately after the 5-minute pulse treatment (FIGURE 7C). These findings, when combined with the findings in FIGURE 7A and FIGURE 7B, above, suggest that the RA-NR-AN-01 conjugates were active and that they were specifically inhibitory for target cells but not non-target cells. Interestingly, when "pulse" treated target cells were returned to culture no long-term inhibitory effects were observed (FIGURE 7D). The results presented in FIGURES 7C and FIGURE 7D again show that Roridin A is non-specifically inhibitory to test cells (i.e., in a manner similar to FIGURE 7A and FIGURE 7B, above) and that its effect on the cells is manifest even after a 16-18 hour recovery period. Thus, the specific effects of the RA-NR-AN-01 conjugates on target cells during a "pulse" treatment appear to be a property of the NR-AN-01 binding protein.

[0228] The results obtained with BO54 arterial smooth muscle cells were similar to those obtained with the A375 cells, above, i.e., free Roridin A showed a dose-response inhibition of protein synthesis in the short-term equated to be 60%, 66%, and 90% of control at 200 ng/ml, 100 ng/ml, and 50 ng/ml; and in long-term the effects on protein synthesis were equated to be 27%, 46%, and 98% of control at the same dosages. In contrast, the 2' or 13'RA-NR-AN-01 showed only 10-20% inhibition for short- or long-term effects on protein synthesis (i.e., >80% of control).

[0229] Thus, the results show a short-term specific reversible effect of Roridin A-conjugated NR-AN-01 on target cells when delivered as a "pulse" treatment. However, since only protein synthesis was evaluated in these experiments, it was possible that cellular metabolic activity might be affected in the cells as a result of the "pulse" treatment. Therefore, additional studies were conducted in which cellular metabolic activity was evaluated following "pulse" treatment.

Effects After 5 Minutes of Exposure: Metabolic Activity

[0230] MTT assays were conducted at 48 hours following a 5-minute exposure of target and non-target cells to RA or RA-NR-AN-01 conjugates. Target cells in these studies included BO54 and A375, and non-target cells included HT29 cells. Sterile 96 well microtiter plates were seeded with 2500 cells/well, wrapped in aluminum foil and incubated in a humidified chamber containing 5% CO₂/95% air for 16-18 hours. Serial two-fold dilutions of Roridin A (RA), 2'RA-HS-NR-AN-01 and 13'RA-HS-NR-AN-01 were prepared from 400 ng/ml to 780 pg/ml, and 100 µl aliquots of the dilutions were dispensed into duplicate wells. After 5 minutes exposure to the test samples, the cells were washed to remove the test samples, and fresh medium was added. The cells were allowed 48 hours of recovery prior to testing: i.e., plates were incubated for 48 hours, and then cellular metabolic activity was determined by adding 20 µl/well of a 5 mg/ml MTT solution. The plates were covered and incubated at 37°C for 4 hours and then the reaction was developed as described above (see EXAMPLE 4, above). The dark blue solubilized formazan reaction product was developed at room temperature after a 16-18 hour incubation. The samples were quantified using an ELISA microtiter plate reader at an absorbance of 570 nm.

[0231] FIGURE 8A graphically depicts the results of *in vitro* studies investigating the effects on BO54 marker-positive smooth muscle cells of a 5 minute exposure to different concentrations of Roridin A (open squares, FIGURE 8A), 2'RA-NR-AN-01 (IVRAN01-2'RA; closed diamonds, FIGURE 8A), or 13' RA-NR-AN-01 (NRAN01-13'RA; closed squares, FIGURE 8A). The experiments were conducted in a manner similar to those described above in regard to FIGURE 7B, but metabolic activity was assayed by MTT assay, i.e., rather than protein synthesis as in FIGURE 7B, and cells were also given 48 hours to recover (rather than 24 hours, as in FIGURE 7B). The results of the experiments are plotted in a manner similar to those described (above) in regard to FIGURE 7A.

[0232] FIGURE 8B graphically depicts the results of *in vitro* studies investigating the effects on A375 m/m marker-positive cells of a 5 minute exposure to different concentrations of Roridin A (open squares, FIGURE 8B), 2'RA-NR-AN-01 (NRAN01-2'RA; closed diamonds, FIGURE 8B), 13'RA-NR-AN-01 (NRAN01-13'RA; closed squares, FIGURE 8B). The experiments were conducted (and the results plotted) in a manner similar to those described above in regard to FIGURE 8A.

[0233] FIGURE 8C graphically depicts the results of *in vitro* studies investigating the effects on HT29 marker-negative cells of a 5 minute exposure to different concentrations of Roridin A (open squares, FIGURE 8C), 2'RA-NR-AN-01 (NRAN01-2'RA; closed diamonds, FIGURE 8C), 13'RA-NR-AN-01 (NRAN01-13'RA; closed squares, FIGURE 8C). The experiments were conducted (and the results plotted) in a manner similar to those described above in regard to FIGURE 8A.

[0234] The results presented in FIGURES 8A-8C show slight differences between the different RA-NR-AN-01 conjugates at the highest doses, but at the lower doses the 2' and 13'RA-NR-AN-01 did not significantly inhibit target cell (i.e., BO54 and A375) or non-target cell (i.e., HT29) metabolic activity over the long-term (i.e., 48 hours). Thus, the results suggest that the short-term inhibition of target cell protein synthesis (FIGURES 7C-7D, above) does not result in long-term metabolic effects on the cells, as measurable in MTT assays. That these assays were able to detect metabolic alterations in cells resulting from a 5 minute exposure is evidenced by the results obtained with free Roridin A. In this case, free Roridin A was non-specifically inhibitory to target and non-target cell types, even when the cells were exposed to the agent for only 5 minutes and then returned to culture for the 48-hour recovery period (FIGURES 8A-8C).

[0235] Thus, the findings with free Roridin A suggest that the MTT assay was capable of detecting metabolic alterations induced during a 5-minute exposure. Taken together these findings suggest that RA-NR-AN-01 conjugates can specifically inhibit target cell activity (i.e., protein synthesis) when administered in a "pulse" treatment, and that these effects were reversible without significant long-term effects on either protein synthesis or cellular metabolic activity (as measured in an MTT assay). These *in vitro* properties of the RA-NR-AN-01 conjugates were judged to be highly useful for inhibition of smooth muscle cell activity *in vivo*. Therefore, animal model studies were next conducted to evaluate the effects of these therapeutic conjugates *in vivo*.

EXAMPLE 6

Determination of Infusion Conditions in an Animal Model

[0236] The therapeutic conjugates described herein are useful for inhibiting stenosis following vascular trauma or disease. In an illustrative example, vascular trauma that is induced during angioplasty is treated during the surgical procedure by removing the catheter used to perform the angioplasty, and inserting a balloon infusion catheter into the vessel. The infusion catheter is positioned with the instillation port (or, alternatively, a permeable membrane region) in the traumatized area of the vessel, and then pressure is applied to introduce the therapeutic conjugate. For example, an infusion catheter with two balloons may be used, and when one balloon is inflated on either side of the trauma site

a fluid space is created that can be filled with a suitable infusion fluid containing the therapeutic conjugate. It has been reported previously that infusion of a horseradish peroxidase (HRP) marker enzyme at a pressure of 300 mm Hg over 45 seconds in dog or human coronary arteries resulted in penetration of the HRP into the vessel wall (Goldman et al., *supra*). However, HRP is a smaller molecule than NR-AN-01 and human and dog coronary arteries are also considerably smaller than the carotid or femoral arteries in the present domestic pig model system. Experiments were therefore conducted to determine, in a domestic pig model system, the infusion conditions suitable for delivery of a therapeutic conjugate to the vascular smooth muscle cells in carotid and femoral arteries. Delivery conditions were monitored by evaluating the penetration of the therapeutic conjugate into the vascular wall, and specific binding of the therapeutic conjugate to the vascular smooth muscle cells in the vessel wall.

[0237] Using an infusion catheter, the coronary and femoral arteries of domestic pigs or non-human primates were infused with NR-AN-01 for 45 seconds to 3 minutes at multiple pressures in the range of about 0.4 atmospheres (300 mm Hg) to 3 atmospheres. After infusion, the vessels were flushed with sterile saline and prepared for immunohistochemistry using HRP-conjugated goat anti-mouse IgG to detect the NR-AN-01 mouse IgG in the vessel wall. It was determined that full penetration was achieved of NR-AN-01 into these vessel walls at a pressure of 3 atmospheres after 3 minutes.

[0238] Immunohistology was also used to determine which animal model systems expressed the target antigen for NR-AN-01. Vascular tissue sections from readily available experimental animal species were exposed to NR-AN-01, washed, and reacted with HRP-conjugated goat anti-mouse IgG. Only non-human primates and swine were found to share the 250 kD NR-AN-01 target antigen with man.

[0239] To determine whether NR-AN-01 could bind in a specific manner to its target antigen *in vivo*, the coronary and femoral arteries of domestic pigs were infused with therapeutic conjugates using an infusion catheter, the infusion sites were flushed with sterile saline, the surgical sites were then closed, and the animals were maintained for an additional 3-5 days. At the end of this time, the vascular infusion sites were excised and prepared for immunohistology, once again using goat anti-mouse IgG to identify NR-AN-01. NR-AN-01 was identified in the vessel wall of swine coronary and femoral arteries 3-5 days after surgery, and the NR-AN-01 appeared to be associated only with vascular smooth muscle cells. These findings suggest that NR-AN-01 is capable of specifically binding to its target antigen *in vivo*.

EXAMPLE 7

Inhibition of Vascular Smooth Muscle Cells *In Vivo*

[0240] Intimal smooth muscle proliferation that follows balloon catheter-induced trauma is a good model to evaluate the therapeutic efficacy of conjugates for inhibiting smooth muscle cell activity *in vivo* in response to vascular trauma, including restenosis following angioplasty. Domestic pigs were used to study the effects of NR-AN-01 (i.e., termed vascular smooth muscle binding protein or simply VSMBP in these studies; and therapeutic conjugates with Roridin A are termed VSMBP - RA). The events which normally follow balloon angioplasty in the porcine artery have been described previously (Steele et al., *Circ. Res.*, 57: 105-112 (1985)). In these studies, dilation of the carotid artery using an oversized balloon (balloon: artery ratio approximately 1.5:1) resulted in complete endothelial denudation over an area of 1.5-2 cm in length. Although this length of traumatic injury was selected in an attempt to minimize thrombosis, there was still marked platelet deposition and thrombus formation. The procedure also resulted in dissection through the internal elastic lamina into the arterial media and necrosis of medial smooth muscle cells. Intimal thickening due to smooth muscle proliferation was apparent 7 days after injury and reached a mean maximum thickness of 85 mm at 14 days. The histological appearance of this neointima is very similar to the proliferative neointimal tissue of human restenosis (Schwartz et al., *Circ.*, 82: 2190-2200 (1990)).

[0241] A single dose test protocol was conducted in domestic pigs with NR-AN-01-Roridin A conjugates. Localized administration of the test conjugates, i.e., through a catheter into a region of traumatized vessel confined by temporary slip ligatures, was designed to reduce systemic toxicity while providing a high level of exposure for the target smooth muscle cells. This intra-artery route of administration in animal model studies simulates the proposed route in human coronary arteries. The test protocol was designed as an initial *in vivo* screening of intra-arteriolar, site specific, catheter administered, vascular smooth muscle binding protein (VSMBP) conjugates.

[0242] Toxicity of free drug was also evaluated, i.e., for pathobiological effects on arteriolar smooth muscle cells. The therapeutically effective dosage of the Roridin A-NR-AN-01 conjugate was determined by *in vitro* studies, and the proper intra-arteriolar administration pressure was determined by administering free MAb and MAb conjugates to animals, as described above in Example 7.

[0243] Six domestic crossbred swine (Duroc X), weanling feeder pigs of approximately 30 pounds body weight, were used in the experiment. The animals were randomly assigned to the following treatment regimen where each pig has four different treatments divided between the right and left carotid and femoral arteries, one of which is a PBS control (Tables 1-3, below).

Table 1

GROUP NO	TREATMENT GROUP	MATERIAL DESCRIPTION
1	CONTROL, VSMBP	VSMBP, 200 µg/ml in PBS, pH 6.5
2	CONTROL, PBS	PBS, pH 6.5, in injection sterile water
3	CONTROL, DRUG	Roridin A, 2.5 µg/ml in PBS, pH 6.5
4	TEST, CONJUGATE	VSMBP-RA2' (200 µg/ml VSMBP & 2.5 µg/ml RA)
5	TEST, CONJUGATE	VSMBP-RA13' (200 µg/ml VSMBP & 3.1 µg/ml RA)
6	TEST, CONJ+RA	VSMBP-RA2' (200 µg/ml VSMBP & 2.5 µg/ml RA) PLUS free Roridin A (2.5 µg/ml)
7	TEST, CONJ+RA	VSMBP-RA13' (200 µg/ml VSMBP & 3.1 µg/ml RA) PLUS free Roridin A (2.5 µg/ml)

Surgical Procedure:

[0244] Test conjugates and control compounds were administered as a single intra-artery infusion at the site of endothelial denuding and trauma induced by a balloon catheter. Both the carotid and femoral arteries were abraded over 1 cm to 2 cm of endothelium by intraluminal passage of a 23 cm, size 3 (femoral) and size 4 (carotid) Uresil Vascu-Flo® silicone occlusion balloon catheter (Uresil Technology Center, Skokie, IL), sufficiently distended with saline to generate slight resistance. This technique produced slight distension of the artery. Following this treatment, proximal and distal slip ligatures, 3-0 silk, were placed near the ends of the abraded region, and a size 8 French, Infant Feeding Catheter (Cutter-Resiflex, Berkeley, CA) attached to an Inflation Pro® (USCI, C.R. Bard, Inc., Billerica, MA) pressure syringe was used to administer the test conjugates and control compounds directly to the denuded segment at a pressure of three atmospheres for three minutes. The slip ligatures were removed after the three minute exposure period and arterial blood flow was re-established. In these studies, branches of the femoral or carotid arteries were ligated with 00 silk suture as required to attain pressurized infusion in the treated region. The largest distal branch of the femoral artery (the saphenous artery) was incised and used as an entry site for the catheters which were then passed into the main femoral artery. Following this catheterization procedure in the main femoral artery, the secondary branch was ligated. In these cases, ligation or incision was used to allow entry of the catheters and the opening was then closed with 3 to 4 sutures of 5-0 monosilamen polybutester (Novafil, D & G Monofil Inc., Monati, PR).

Follow-up Procedures:

[0245] Following surgery, the pigs were kept in 3 X 5 foot indoor runs with cement floors during the quarantine and surgical recovery periods. They were then transferred to indoor/outdoor pens for the remainder of the five week healing period prior to collection of tissues for histology.

[0246] The animals recovered normally from surgery with no evidence of hemorrhage or inflammation at the surgical sites. All six animals were examined 5 to 6 days after treatment with a doppler stethoscope, and all arteries in each of the animals were patent. Post treatment all animals had normal appetite, activity and weight gain.

Gross Pathology and Histological Evaluation:

[0247] Five weeks following the traumatization and treatment of the arteries, the animals were sedated with 0.6 ml Telazol® (tiletamine hydrochloride; A.H. Robins Co., Richmond, VA) and 0.5 ml xylazine (Lloyd Laboratories, Shendoah, IA) per 30 lb body weight by intramuscular injection, heparinized (i.v. 2 ml sodium heparin, 1000 units/ml), and euthanized by i.v. pentobarbital. Both the right and left carotid and femoral arteries were removed with normal vessel included both proximal and distal to the treated segment. The arteries were measured and the location of ligatures and gross abnormalities noted. The arteries were transected at 2 mm intervals and arranged in order in cryomolds with O.C.T. (optimum cutting temperature) compound (Tissue Tek®, Miles Laboratories Inc., Elkhart, IN) and frozen in liquid nitrogen. The blocks were sectioned at 5 microns and stained with H&E, Massons Trichrome and Movats Pentachrome for morphological studies. Sections were also used for immunohistological staining of vascular smooth muscle.

[0248] Histological examination of the step sections of the arteries revealed marked inhibition of intimal smooth muscle proliferation in the regions traumatized and treated with RA-NR-AN-01 conjugates (Table 2). This inhibition was evident even at sub-gross evaluation of the vessels. The inhibition of intimal smooth muscle cell proliferation was produced with minimal or no histological evidence of smooth muscle cell death in the artery wall. A cross-sections of

one such traumatized artery is provided in FIGURES 9A and 9B.

Table 2

(High pressure)	1	1(1)
(Low pressure)	1	1(1)

*Intimal SMC Hypertrophy: intimal smooth muscle cell hypertrophy scored on a scale from 1+ (minimal) to 4+ (maximal).

[0249] The results presented in FIGURE 9A show (at 160x magnification) a cross-sectional of an untreated artery 5 weeks after angioplasty. Dominant histological features of the artery include displacement of the endothelium (see #1 in FIGURE 9A) away from the internal elastic lamina (see #2, FIGURE 9A), apparently due to intimal smooth muscle proliferation (see #3, FIGURE 9A).

[0250] The results presented in FIGURE 9B show (at 160x magnification) a cross-section of a treated artery 5 weeks after angioplasty and infusion of the RA-NR-AN-01 therapeutic conjugate. The vessel in this section was subjected to greater mechanical stresses than the vessel shown in FIGURE 9A, with multiple sites where the external elastic membrane was ruptured and associated proliferation of smooth muscle cells in the outer layers of the media was observed (i.e., see #4 in FIGURE 9B). Treatment with therapeutic conjugate inhibited intimal hypertrophy, as evidenced by the lack of displacement of the endothelium (see #1, FIGURE 9B) from the internal elastic lamina (see #2, FIGURE 9B). Surprisingly, this inhibitory effect on intimal smooth muscle cells was accomplished without inhibiting hypertrophy of medial smooth muscle cells in the areas where the external elastic membrane was ruptured (see #4, FIGURE 9B).

[0251] This is a highly fortunate result because wound healing proceeds in the treated vessel without the adverse consequences of intimal hyperplasia and stenosis, or necrosis of smooth muscle cells in the media.

[0252] In these histological studies, comparisons were also made of the effectiveness of both the 2' and the 13' - Roridin A conjugate with the finding that the 13' conjugate (i.e., 13'RA-HS-NR-AN-01) appeared to be more active in inhibiting intimal hyperplasia of smooth muscle cells than the 2' conjugate (i.e., 2' RA-HS-NR-AN-01). In this study, low pressure infusion of the 13' conjugate appeared to inhibit smooth muscle proliferation more effectively than high pressure and the 13' conjugate also appeared to be more effective than the 2' conjugate.

[0253] In FIGURE 9B, therapeutic conjugate administered at the site following angioplasty resulted in approximately 95% inhibition of the smooth muscle hypertrophy that restricted the lumen of the untreated vessel (FIGURE 9A). Significantly, the therapeutic conjugate exerted its effects on the smooth muscle cells migrating from the medial smooth muscle layers into the intima, without affecting either endothelium, or producing any signs of necrosis (i.e., cell death) in the smooth muscle cells in the medial layers of the arterial wall. Studies also failed to show any histological signs of mononuclear infiltration or fibrosis such as might result from toxic effects on the vessel wall. Also, visible signs of healing were observed in the intimal layers of treated vessels and with re-growth of endothelium observed, i.e., endothelial cells growing over the thin layer of smooth muscle cells in the intima that lie between the endothelium and internal elastic lamina (i.e., #1 and #2, FIGURE 9B). These combined histological observations suggest the highly desirable features of wound healing, re-growth of endothelium and improved vascular strength following treatment with a therapeutic conjugate that inhibits smooth muscle hyperplasia in the intimal layers of the vessel.

EXAMPLE 8

Vascular Smooth Muscle Cell *In vitro* DNA and Protein Synthesis Inhibition

[0254] The ability of various agents to inhibit DNA synthesis and protein synthesis in vascular smooth muscle cells was tested. ³H-leucine and ³Hthymidine uptake and cytotoxicity assays were conducted in accordance with the following protocols.

[0255] 5 minute exposure ^3H -leucine uptake: Vascular smooth muscle cells at 40,000 cells/ml were seeded in sterile 24 well plates at 1 ml/well. The plates were incubated overnight at 37°C, 5% CO₂, 95% air in a humidified atmosphere (saturation). Log dilutions of the therapeutic agent of interest were incubated with the vascular smooth muscle cells for 5 minutes or 24 hours. Samples of the therapeutic agents were diluted in DMEM:F-12 medium (Whittaker Bioproducts, Walkersville, Maryland) with 5% fetal bovine serum (FBS, Gibco BRL, Gaithersburg, MD) and 5% Serum Plus® (JRH Biosciences, Lenexa, KS). Following therapeutic agent incubation, the solution was aspirated, and 1 ml/well of 0.5 microcurie/ml ^3H -leucine in leucine-free DMEM (Dulbecco's Modified Eagle's Medium) with 5% Serum Plus® was added. The plates were re-incubated overnight at 37°C, 5% CO₂ in a humidified atmosphere. The cells were visually graded using an inverted microscope using a scoring scale to determine viability and cell number. The 1 to 3 grade is based upon percent of cell viability and number compared to control wells, with 3=100%, 2=70% and 1=0%-70%. A record of this scoring assisted in determining the immediate cytotoxic effect of the therapeutic agents. The medium was then aspirated, and the cells were washed twice with cold 5% TCA. 400 microliters of 0.2 M NaOH was added per well, and the plates were incubated for two hours at room temperature on a rotating platform. 200 microliters per well of the cell solution was transferred into plastic scintillation vials (Bio-Rad Laboratories), and 4 milliliters of Bio-Safe® II liquid scintillation fluid (Research Products InterCorp., Mount Prospect, IL) was added prior to vortexing. Vials were counted on a Beckman LS2800 liquid scintillation counter interfaced with Beckman "Data Capture" software for conversion to a Lotus 1-2-3® file and analysis using Lotus 1-2-3®.

5 minute exposure; ^3H -thymidine uptake: Vascular smooth muscle cells were incubated in complete medium with 5% FBS (Gibco) overnight at 37°C in a humidified, 5% CO₂ environment in sterile 24 well plates. The medium was aspirated from the wells and serum free medium supplemented with growth factors (DMEM: F-12 basal medium supplemented with growth factor cocktail, catalog number 11884, which contains insulin (5 micrograms/ml), transferrin (5 micrograms/ml) and sodium selenite (5 nanograms/ml), available from Sigma Chemical, St. Louis, Missouri) was added. Cells were incubated in this medium for 24 hours. For a 5 minute therapeutic agent exposure, log dilutions of the therapeutic agent were incubated with the cells in complete medium. After 5 minutes and medium aspiration, 1 ml/well of 1.0 microcurie/ml ^3H -thymidine dispersed in complete medium was added. The 24 hour exposure involved incubation of the cells with 1 ml/well of 1.0 microcurie/ml of ^3H -thymidine dispersed in complete medium and log dilutions of the therapeutic agent being tested. In both exposure trials, the cells were then incubated overnight at 37°C in a humidified, 5% CO₂ environment. The cells were visually scored for viability and cell number. Cells were washed and prepared for transfer into plastic scintillation vials as described for the ^3H -leucine protocol. Vials were counted on a Beckman LS2800 liquid scintillation counter interfaced with Beckman "Data Capture" software for conversion to a Lotus 1-2-3® file and analysis using Lotus 1-2-3®.

[0256] These protocols are amenable to use with other target cell populations, especially adherent monolayer cell types. Morphological Cytotoxicity Evaluation-Pulsed Exposure: Vascular smooth muscle cells were seeded at 4.0 x 10⁴ cells/ml medium/well on a commercially prepared four well slide (Nunc, Inc., Naperville, Illinois). Enough slides were seeded to accommodate two pulsed exposure lengths (5 minutes and 24 hours) and prescribed increment evaluation points (24 hours to 128 hours). All slides were run in duplicate to reveal any assay anomalies. The therapeutic agent was diluted in the same medium used in the ^3H -leucine and ^3H -thymidine assays. Each four well slide was concentration bracketed to one log greater concentration (well "B"), one log lower concentration (well "D") of the minimal effective concentration (well "C"), as determined by the ^3H -leucine and ^3H -thymidine assays described above. As a control for normal morphology, one well (well "A") was left untreated (medium only). Incubation took place in a 37°C, 5% CO₂ humidified incubator. After each of the two (5 minutes and 24 hours) exposure points, the agent medium was aspirated from each well, including the untreated well. One milliliter of fresh medium was then added to replace the aspirated medium. Re-incubation followed until each of the incremented evaluation points were achieved. At those points, the medium was aspirated and subsequently replaced with 1 ml of 10% neutral buffered formalin for one hour to allow for proper fixation. These fixed slides were stained by hematoxylin (nuclear) and eosin (cytoplasmic) for morphologic evaluation and grading.

Results:

[0257] The results of the 24 hour ^3H -leucine protein inhibition assay and the 24 hour ^3H -thymidine DNA synthesis inhibition assay are shown in Figs. 10A-10D for suramin, staurosporin, nitroglycerin and cytochalasin B, respectively. All of the tested compounds showed an available therapeutic range (area under the curve of ^3H -leucine assay is greater than that resulting from the ^3H -thymidine assay), indicating usefulness in the practice of sustained release dosage form embodiments. More specifically, the compounds inhibited the ability of vascular smooth muscle cells to undergo DNA synthesis in the presence of 5% FBS to a greater extent than they inhibited protein synthesis of vascular smooth muscle cells. The protein and DNA synthesis inhibitory effects of suramin, staurosporin, nitroglycerin and cytochalasin B during a 5 minute and 24 hour pulsed exposure are shown in Figure 10 A-D, respectively.

EXAMPLE 9

Specific Binding and Internalization of Targeted Particles by Vascular Smooth Muscle Cells

5 [0258] The ability of vascular smooth muscle cells to bind and internalize particles coated with binding protein or peptide was demonstrated with monoclonal antibody (NR-AN-01) coated gold beads both in vitro and in vivo.

10 The vascular smooth muscle cell tissue cultures (BO54), an antigen positive control cell line (A375) and an antigen negative control cell line (HT29) were incubated with 10 nm gold beads, with one group coated with NR-AN-01 and a second, uncoated control group. The cells were exposed to the beads as monolayer and cell suspension cultures, and were examined at six time points (i.e., 1 minute, 5 minutes, 15 minutes, 30 minutes, 60 minutes and 24 hours) for binding and internalization by electron microscopy.

15 [0259] Table 3 shows the results of the experimentation, indicating that the binding to the cell surface is specific. The relative grading system used throughout Table 3 represents a subjective assessment of particle binding, wherein 0 = none; 1 = minimal; 2 = mild; 3 = moderate; and 4 = marked. If aggregates of particles settled on the monolayer surface of both the smooth muscle cells and the control cells, the particles were nonspecifically internalized by macro and micro phagocytosis. When the cells were maintained in a cell suspension, non-specific internalization was minimal or absent. Non-specific adherence of gold beads devoid of NR-AN-01 to surface mucin produced by HT29 cells was observed, resulting in modest non-specific internalization thereof. Vascular smooth muscle cell uptake of NR-AN-01 targeted gold beads was highly specific in cell suspension cultures.

[0260] FIGURE 11 shows a tangential section parallel to the inner surface of a smooth muscle cell characterized by numerous endocytic vesicles, several of which contain antibody coated gold beads in the process of being internalized by the cell. These endocytic vesicles with particles attached to cell surface antigens were stimulated to fuse with lysosomes at a higher than expected rate for normal cell surface membrane recycling. The resultant marked accumulation of internalized particles was observed at the 24 hour time point and is shown in FIGURE 12.

[0261] The targeted gold bead vascular smooth muscle cell surface binding, internalization and lysosome concentration was observed in vivo as well. NR-AN-01 coated gold beads were infused via intravascular catheter, open ended with treated area occluded proximally and distally with slip ligatures, at 3 atm pressure applied for 3 minutes into the wall of a pig femoral artery immediately following balloon trauma. The bead internalization rate varied with the degree of damage sustained by the vascular smooth muscle cell during the balloon trauma. Cells with minimal or no damage rapidly internalized the particles by endocytosis and phagocytosis, concentrating the internalized particles in lysosomes. Cells that were killed by the trauma exhibited surface bead binding. Cells that were damaged by the trauma but survived were characterized by bead surface binding with delayed internalization and lysosome concentration. FIGURE 13 shows particulate concentration in the lysosomes in vivo at one week following bead administration.

EXAMPLE 10

Vascular Smooth Muscle In Vitro DNA and Protein

Synthesis Inhibition By Staurosporin and Cytochalasin

[0262] The ability of staurosporin and cytochalasin to inhibit in vitro DNA and protein synthesis in vascular smooth muscle cells was tested. ^3H -leucine and ^3H -thymidine uptake and cytotoxicity assays were conducted in accordance with the following protocols.

Cultured Cells:

[0263] BO54 cells (baboon smooth muscle cells) were derived from explants of aortic baboon smooth muscle cells. Cells were expanded in DMEM (Dulbecco's Modified Eagle's Medium):F-12 medium (Whittaker Bioproducts, Walkersville, Maryland) with 5% fetal bovine serum (FBS, Gibco) and 5% Serum Plus® (JRH Biologicals) ("complete medium"), and a seed lot of cells was frozen in liquid nitrogen for future use at passage seven.

5 Minute Exposure; Protein Synthesis Assay:

[0264] Vascular smooth muscle cells at 40,000-50,000 cells/ml were seeded and processed as described in Example 8, "5 minute exposure; ^3H -leucine uptake." Log dilutions of staurosporin (200 ng/ml, 20 ng/ml, 2 ng/ml, 0.2 ng/ml and 0.02 ng/ml) were dispersed in complete medium. For cytochalasin B, log dilutions at 20 $\mu\text{g/ml}$, 2.0 $\mu\text{g/ml}$, 0.2 $\mu\text{g/ml}$, 0.02 $\mu\text{g/ml}$ and 0.002 $\mu\text{g/ml}$ were dispersed in complete medium. Complete medium was then added to the control wells. One ml/well of each therapeutic agent dilution was added in quadruplicate wells, and the agent of interest was incubated with the vascular smooth muscle cells for 5 min at room temperature in a sterile ventilated hood. Following therapeutic agent incubation, the wells were subsequently treated as described in Example 8, "5 minute exposure; ^3H -leucine uptake."

5 Minute Exposure; DNA Synthesis Assay: Vascular smooth muscle (BO54) cells were seeded and processed in 24 well plates, as described above under "5 Minute Exposure: Protein Synthesis Assay." After 5 min incubation with the test therapeutic agent, the medium was aspirated and 1 ml/well of 1.0 $\mu\text{Ci/ml}$ ^3H -thymidine (rather than ^3H -leucine) dispersed in complete medium was added. The cells were then incubated overnight at 37°C in a humidified, 5% CO_2 environment. The toxic effect of the therapeutic agent was then determined, as described in the Protein Synthesis Assay, above.

24 and 120 Hour Exposure; Protein Synthesis Assay: Vascular smooth muscle (BO54) cells at 20,000 cells/ml were seeded in sterile 24 well plates and incubated in complete medium (1 ml/well) overnight at 37°C, 5% CO_2 , 95% air in a humidified atmosphere (saturation). Log dilutions of staurosporin (100 ng/ml, 10 ng/ml, 1 ng/ml, 0.1 ng/ml and 0.01 ng/ml) were dispersed equentially in the two media, as described below. For cytochalasin B, log dilutions at 10 $\mu\text{g/ml}$, 1.0 $\mu\text{g/ml}$, 0.1 $\mu\text{g/ml}$, 0.01 $\mu\text{g/ml}$ and 0.001 $\mu\text{g/ml}$ were dispersed sequentially in the two media, as described below:

Medium (1) = Complete medium; and

Medium (2) = DMEM (leucine-free) with 0.5 $\mu\text{Ci/ml}$ ^3H -leucine. Medium (2) is used for the final 24 hour incubation period of the experiment. More specifically, in the 24 hour assay, each agent was diluted in Medium (2), as noted above. Medium (1) was aspirated from the wells, and aliquots of therapeutic agent dilutions in Medium (2) were

added in quadruplicate to the appropriate wells. Medium (2) was then added to the control wells.

[0265] In the 120 hour assay, each agent was diluted in Medium (1), as noted above. Medium (1) was aspirated from the wells, and aliquots of agent dilutions in Medium (1) were added in quadruplicate to the appropriate wells. Medium (1) was then added to the control wells. The medium was changed every 24 hours, and fresh agent was added to the test wells. At 96 hr, (i.e., the fourth day), each agent was diluted in Medium (2), as noted above. Medium (1) was aspirated from the wells, and aliquots of agent dilutions in Medium (2) were added in quadruplicate to the appropriate wells. Medium (2) was then added to the control wells.

[0266] The test agents in ^3H -leucine (and controls) were incubated overnight at 37°C , 5% CO_2 in a humidified atmosphere. The toxic effect of the agents was then determined, as described in the 5 Minute Exposure: Protein Synthesis Assay, described above. In addition, the changes in cells at each dilution were photographed using a Zeiss microscope (Zeiss, West Germany) at 320X. The medium was then aspirated, and the cells were processed with TCA, as described above.

24 and 120 Hour Exposure, DNA Synthesis Assay: This assay was performed according to the procedure described for "24 and 120 Hour Exposure; Protein Synthesis Assay", except Medium (2) in this 24 & 120 hr DNA Synthesis Assay is:

Medium (2) = Complete Medium with $1.0\ \mu\text{Ci/ml}$ ^3H -thymidine. Medium (2) is used in the final 24 hour incubation of the experiment.

[0267] These protein and DNA synthesis assays are amenable for use with other target cell populations, especially adherent monolayer cell types.

[0268] Results: The minimum effective dose (MED) of each agent was determined as a percentage of the control that was treated with medium only; 50% of control values was chosen as the cytotoxicity benchmark. At a 5 min exposure, staurosporin demonstrated an MED of 100 ng/ml in the protein synthesis assay and 1 ng/ml in the DNA assay. The 24 hour MED for staurosporin was 10 ng/ml in the protein synthesis assay and 1 ng/ml in the DNA synthesis assay. Both assays gave an MED of 1 ng/ml for a 120 hour exposure of staurosporin.

[0269] At a 5 minute exposure, cytochalasin B demonstrated an MED of $10\ \mu\text{g/ml}$ in the protein synthesis assay as well as in the DNA assay. The 24 hour MED for cytochalasin B as $1.0\ \mu\text{g/ml}$ in the protein synthesis assay and $0.1\ \mu\text{g/ml}$ in the DNA synthesis assay. Both assays gave an MED of approximately $0.1\ \mu\text{g/ml}$ for a 120 hour exposure of staurosporin.

[0270] Cytochalasin C and cytochalasin D were tested at 24 and 48 hour exposures using the same dilutions as described for cytochalasin B, above. At 24 hours, cytochalasin C demonstrated an MED of $1.0\ \mu\text{g/ml}$ in the protein synthesis assay and an MED of $0.01\ \mu\text{g/ml}$ in the DNA synthesis assay. At 48 hours, cytochalasin C demonstrated an MED of $0.1\ \mu\text{g/ml}$ in the protein synthesis assay and $0.01\ \mu\text{g/ml}$ in the DNA synthesis assay. Cytochalasin D demonstrated an MED of $1.0\ \mu\text{g/ml}$ in the 24 hour protein synthesis assay and an MED of $0.1\ \mu\text{g/ml}$ in the 24 hr DNA synthesis assay. A 48 hour exposure to cytochalasin D gave an MED ranging between 0.1 and $0.01\ \mu\text{g/ml}$ in both the protein synthesis and DNA synthesis assays.

EXAMPLE 11

Vascular Smooth Muscle Cell Migration Inhibition

[0271] Scratch assays to determine the extent of smooth muscle cell migration inhibition by cytochalasin B were performed in accordance with the following protocol:

[0272] Vascular smooth muscle cells (BO54) were derived from explants of baboon aortic smooth muscle, as described in Example 10. The cells were grown in flat bottom, six well tissue culture plates, which hold about 5 ml of medium. The vascular smooth muscle cells were plated at 200,000 cells/well and placed at 37°C in a humidified 5% CO_2 incubator for 18 hours. The wells were then scratched with a sterile portion of a single edge razor blade that was held by clamp or pliers and was brought aseptically into contact with the bottom of the well at a 90° angle. The cells from a small area along the scratch were removed by a sterile cotton tipped applicator while the blade was in contact with the bottom of the well. After incubation, the presence of cells in the "scratched" area is indicative of cell migration across the scratch line. A control incubation showed significant cellular migration, and serves as the standard against which the migration of cells exposed to the therapeutic agent is compared.

[0273] Briefly, a stock solution of cytochalasin B (Sigma Chemical Co.) in dimethyl sulfoxide (DMSO) at 1 mg/ml was prepared. Test dilutions of cytochalasin B or control medium were added. Each experiment included two sets of plates:

A set: Test agent exposure for 1, 3, 6, 8 and 10 days only; and

B set: Test agent exposure for 1, 3, 6, 8 and 10 days, followed by a seven day recovery time with control medium.

Both sets of plates were fixed (10% formalin in PBS) and stained (0.02% crystal violet) at the end of the timed exposures. Test concentrations for cytochalasin B were 1, 0.1 and 0.01 $\mu\text{g/ml}$, and a negative medium control was included. Fresh medium and drug were supplied 3 times per week.

[0274] Table 4 shows the results of these experiments. In this Table, "M" indicates Migration Grade, wherein - = no migration; +1 = minimal; +2 = mild; +3 = moderate; and +4 = marked (maximum density; limit of cell contact inhibition) migration of vascular smooth muscle cells into the cleared area adjacent to the scratch. In this Table, "T" denotes a morphological Toxicity Grade, wherein - = no toxicity; +1 = minimal; +2 = mild; +3 = moderate; and +4 = marked toxicity. The migration results are expressed as "Grade in the Cleared Area of the Well / Grade in an Undisturbed Region of the Well." The toxicity values represent a grade for all cells in each well.

[0275] The data indicate that cytochalasin B inhibits the migration (+1 to +2) of vascular smooth muscle cells into the cleared area adjacent to the scratch at a dose of 0.1 $\mu\text{g/ml}$ with only minimal (- to +1) morphological toxicity. The data also show that the treated cells (0.1 $\mu\text{g/ml}$) regain the ability to migrate (+3 to +4) following removal of the therapeutic agent, even after 10 days of continuous exposure to the therapeutic agent.

Agent Cytotoxic Effects on Vascular Smooth Muscle Cells - Pulse and Continuous Exposure

[0276] Vascular smooth muscle cells were exposed to an agent in one of two exposure formats:

Pulse exposure:

[0277] The pulse exposure protocol is described in Example 8 above (see "Morphological Cytotoxicity Evaluation - Pulsed Exposure").

Continuous exposure:

[0278] The same methodology is used for continuous exposure morphological cytotoxicity evaluation as for the pulse exposure, except that the test wells were continuously exposed to agent in medium during the exposure period. The medium and agent were aspirated from each well daily, including from the untreated control well, and were replaced with 1 ml of fresh medium and agent (or medium alone for control wells). Reincubation followed, until each of the incremental evaluation points of the long term continuous exposure protocol was achieved. These incremental evaluation time points were at 6, 24, 48, 72, 96, 120, 168, 216 and 264 hours. At the designated time period, the appropriate cells were fixed, stained and evaluated as in the pulse exposure protocol. The results of a continuous exposure experiment are shown in Table 5 for suramin, staurosporin and cytochalasin B. The 5 min and 24 hr data presented in Table 5 are correlates of the data contained in Figures 10A, 10B and 10C.

Table 5
MORPHOLOGICAL CYTOTOXICITY ASSAY
Drug & Dose

Exposure Protocol	Cytochalasin B				Suramin				Staurosporine			
	10 µg	1 µg	0.1 µg	0.01 µg	10 mg	1 mg	0.1 mg	0.01 mg	100 ng	10 ng	1 ng	0.1 ng

Continuous 264 hrs	-	4	1	0	-	5	4	0	-	4	2	1

[0279] At an in vitro effective dosage, cytochalasin B (1 µg/ml; an anti-migration/contraction effective dose) and

staurosporin (1 ng/ml; an anti-proliferative effective dose) exhibited a cytotoxicity grade of 1 (minimal) and 2 (mild), respectively. Independent studies have indicated that a grade of 3 (moderate) or less is preferred for a cytostatic, anti-proliferative agent of the present invention.

EXAMPLE 13

In Vivo BRDU Assay: Inhibition of Vascular Smooth Muscle Cell Proliferation

[0280] BRDU assay: In vivo vascular smooth muscle proliferation was quantitated by measuring incorporation of the base analog 5-bromo-2'-deoxyuridine (BRDU, available from Sigma Chemical Co.) into DNA during cellular DNA synthesis and proliferation. BRDU incorporation was demonstrated histochemically using commercially available anti-BRDU monoclonal antibodies. The 1 hour pulse labeling permits assessment of the number of cells undergoing division during the pulse period.

[0281] The BRDU pulse labeling protocol described above is used as a standard evaluation technique with in vivo pig vascular studies. Following surgical and treatment procedures (discussed, for example, in Examples 7 and 11 herein) and a post-surgical recovery period, pigs were sedated and pulsed with BRDU 1 hour prior to tissue collection.

[0282] Briefly, the pigs were sedated with tiletamine hydrochloride and xylazine (as in Example 7, "Gross Pathology and Histological Evaluation") by intramuscular injection. BRDU was then administered intravenously via the lateral ear vein. Two ml of BRDU at a concentration of 50 mg/ml was administered to each 30-40 lb pig. One hour later, the pigs were sacrificed by intravenously administered pentobarbital. Test artery segments were then removed (a segment included normal vessel located proximally and, if possible, distally with respect to the treated artery segment). The artery segments were transected at 2 mm intervals; arranged in order in cryomolds with O.C.T. (optimum cutting temperature) compound (Tissue Tek®, Miles Laboratories, Inc., Elkhart, IN); and frozen in liquid nitrogen. The blocks were sectioned at 5 microns and immunohistologically stained to detect BRDU using the following procedure.

BRDU-labeled cell detection: After BRDU (1 g BRDU diluted in 17 ml sterile water and 3 ml 1 N NaOH) pulse labeling and test artery segment removal and sectioning (as above), immunohistochemical staining with anti-BRDU monoclonal antibody provides a visual means of determining a mitotic index over a specified time period. The immunohistochemical staining method was performed as follows:

- 1) 5 μ m sections of test artery were dehydrated in cold acetone (-20°C) for 10 minutes;
- 2) Sections were mounted on glass microscope slides, and the slides were dried in a 37°C oven for 10 minutes;
- 3) Slides were rehydrated in PBS for 10 minutes;
- 4) Slides were subjected to Feulgen's acid hydrolysis using 1 N HCl, wherein two aliquots of 1 N HCl are preheated to 37°C and 60°C prior to proceeding;
- 5) Slides were rinsed with 1 ml of 1 N HCl at 37°C for 1 min;
- 6) Slides were transferred to 60°C 1 N HCL for 15 min;
- 7) Slides were rinsed with 1 ml of 1 N HCl at 37°C for 1 min;
- 8) Slides were washed with room temperature PBS, using 3 changes of PBS at 5 min intervals;
- 9) Endogenous, cross-reactive sites on the sections were blocked with normal goat serum (1:25 in PBS) for 20 min;
- 10) Slides were washed with PBS, as in step 8;
- 11) Sections were incubated with mouse anti-BRDU antibody (DAKO Corporation, Carpinteria, CA) at 10 μ g/ml for 30 min;
- 12) Slides were washed with PBS, as in step 8;
- 13) Sections were incubated with horseradish peroxidase-labeled (HRPO) goat anti-mouse IgG, (Jackson ImmunoResearch Laboratories, Inc., West Grove, PA; diluted 1:20 in PBS) and 4% human AB serum for 30 min;
- 14) Slides were washed with PBS, as in step 8;
- 15) Sections were incubated with chromogen (3,3'-diaminobenzidine (DAB; Sigma) at 5 mg/ml in 200 ml PBS) and 200 μ l of 30% H₂O₂ for 10 min;
- 16) Slides were washed with PBS, as in step 8;
- 17) Samples were counterstained with Gill I hematoxylin (Gill I Lemer Laboratories, Pittsburgh, PA; 30 dips);
- 18) Slides were washed with PBS, as in step 8; rinsed with a bluing solution (1 gm lithium carbonate in 500 ml dH₂O); washed with deionized water; and
- 19) Test samples were then dehydrated, cleared and coverslipped.

[0283] At the conclusion of this procedure, a positive immunohistological stain exhibits a brown color at the site(s) of reactivity.

[0284] Cytocidal agents inhibited BRDU uptake relative to a PBS control; however, cytochalasin B and staurosporin inhibited BRDU uptake (i.e., cell proliferation) without killing the vascular smooth muscle cells. The number of vascular

smooth muscle cells labeled with BRDU was assigned a grade at 400X magnification as follows:

- 1 = \leq 1/high power field (HPF);
 2 = 2 to 5/HPF;
 3 = $>$ 5 to \leq 10/HPF; and
 4 = $>$ 10/HPF.

[0285] Both cytochalasin B and staurosporin inhibited proliferation for 24 hours following balloon trauma (grade 1), yielding a BRDU labeling grade equivalent to that of a pre-trauma baseline (grade 1). PBS and monoclonal antibody controls exhibited grade 2.5 to 4 BRDU labeling during the same time period. At 4 days post-trauma, arteries treated with cytochalasin B or staurosporin, as well as PBS and monoclonal antibody controls, exhibited a BRDU labeling grade of 4. The anti-proliferative, non-cytocidal properties of cytochalasin B and staurosporin suggest that these agents are amenable to sustained release dosage formulations for reduction of vascular stenosis.

EXAMPLE 14

Direct Conjugation of NR-AN-01 Antibody to Carboxylic Functional Groups of a Latex Particle

[0286] Antibody-coated latex particles (a model of an antibody-coated, sustained release dosage form) may be obtained using the following aseptic technique:

Conjugation:

[0287] To 4 ml 0.05 M sodium borate, pH 8.5, containing 0.01% Tween-20® (polyoxyethylene sorbitan monolaurate, Sigma) is added 0.5 ml PBS containing 5 mg NR-AN-01 monoclonal antibody. To this solution at room temperature is added, with vortexing, 2.5 ml of an aqueous suspension containing 50 mg of 1 μ m diameter carboxylated latex particles. Immediately thereafter, 0.50 ml of water containing 100 mg of freshly dissolved 1(3-dimethyl-aminopropyl)3-ethyl carbodiimide HCl is added with vortexing. The solution is then incubated with shaking for 1-2 hr at room temperature. The reaction mixture is then diluted with 50 ml of 50 mM phosphate buffer, pH 6.6, containing 0.2% gelatin stabilizer (phosphate/gelatin buffer). The mixture is centrifuged at 40,000 x g for 2 hr at 4-10°C. The supernatant is decanted, and the pellet is resuspended in 50 ml phosphate/gelatin buffer using low level sonication for 10 sec. Centrifugation is repeated, and the pellet is resuspended two times, followed by resuspension in the phosphate/gelatin buffer. The conjugated particles are then lyophilized using standard protocols and sorbitol excipients.

Characterization:

[0288]

(a) Sizing: Particle size homogeneity is assessed by laser anisotropy or, for particles larger than 1 μ m, by microscopic examination.

(b) Specific Binding Assessment: Specific binding to smooth muscle cells is determined by histological examination of tissue or cell pellet microtome slices after incubation of protein/peptide conjugates with conjugated particles, with or without blocker protein/peptide included in the incubation mixture. Preferred detection techniques include second antibody assays (i.e., anti-mouse Ig) or competition assays (i.e., radioscintigraphic detection in conjunction with radioisotopically labeled protein/peptide conjugates).

(c) Assessment of the extent of protein/peptide derivitization: This determination is performed by coating the latex particles with radioisotopically labeled antibody, followed by detection of radioactivity associated with the coated particles.

[0289] The characterization of antibody-coated particles is described in Table 6.

Table 6

Characterization of NR-AN-01-Coated Latex Particles			
Particle Diameter	Offering of Ab/Particle	μ g Ab Bound/ Ab Molecules	
		5 mg Latex	Per Particle
1.2 μ m	40,000	42	3520

Table 6 (continued)

Characterization of NR-AN-01-Coated Latex Particles			
Particle Diameter	Offering of Ab/Particle	μg Ab Bound/ Ab Molecules	
		5 mg Latex	Per Particle
1.2 μm	84,000	66	5470
0.4 μm	32,000	99	3160
0.4 μm	64,000	140	4550

[0290] The particle aggregation effect of pH during antibody conjugation is presented in Table 7.

Table 7

Effect of pH During Antibody Conjugation - Particle Aggregation			
Particle Diameter	pH*During Conjugation	Particle Aggregation** +Tween 20® -Tween 20®	
1.2 μm	8.5	< 5%	< 2.5%
1.2 μm	7.0	\approx 20%	\approx 10%
1.2 μm	5.5	10%	100%
0.4 μm	8.5	<10%	< 5%
0.4 μm	7.0	\approx 30%	\approx 20%
0.4 μm	5.5	100%	100%
0.1 μm	8.5	<20%	<10%
0.1 μm	7.0	\approx 50%	\approx 40%
0.1 μm	5.5	100%	100%

* Using 50 mM MES (pH 5.5); phosphate (pH 7.0); or borate (pH 8.5) buffer, as described.

** As assessed by microscopic examination, on a scale of 0-100%.

[0291] These data suggest that proteins or peptides may be directly conjugated with sustained release dosage forms of the present invention. More specifically, poly-lactic/glycolic acid particulates having terminal carboxylic acid groups will be conjugated according to the procedure described herein or the alternative procedures described in the specification hereof.

EXAMPLE 15

In Vivo Studies of Cytochalasin B

[0292] Biodistribution of Cytochalasin B. To determine the biodistribution of cytochalasin B, mice were injected (i.p.) with 50 mg/kg cytochalasin B. Control mice were injected with DMSO/Tween 20/carboxymethyl cellulose ("vehicle"). The mice were sacrificed at 3, 12, 24 and 72 hours after cytochalasin B or vehicle administration. Organs were removed, homogenized, extracted and the amount of cytochalasin B in tissues quantitated by HPLC. About 75% of the cytochalasin B remained in the peritoneal cavity or at the injection site. Of the organs tested, the highest amount of cytochalasin B was found in the liver. Subsequent analyses showed that the maximum tolerated dose for cytochalasin B was 50 mg/kg, and that this dose may be administered every second day.

[0293] Cytochalasin B was also administered intravenously to mice at 3.5 mg/kg (in methanol or Tween 20/carboxymethyl cellulose). Mice were sacrificed at 2 minutes, 15 minutes, 30 minutes, 3 hours and 12 hours after cytochalasin B administration and tissue extracts analyzed for cytochalasin by TLC. The maximal recovery of cytochalasin B from tissue extracts was 32%. The data showed that cytochalasin B was localized to the lung and the injection site, and that 3.5 mg/kg of cytochalasin B resulted in no acute toxicity. By 12 hours after administration, there were very low levels of cytochalasin B in tissues.

[0294] ^3H -cytochalasin B (2 μg ; 30 $\mu\text{Ci}/\mu\text{g}$) was injected i.v. into BALB/c mice having urinary bladders that had been externally ligated. Animals were sacrificed at 15 minutes, 30 minutes, 2 hours or 16 hours post-injection. Organs were removed, blotted, weighed, air dried and assayed for radioactivity. Fifty - 73% of the total injected dose was accounted for in the tissues sampled (blood, heart, brain, muscle, bone, lung, liver, spleen, stomach, kidney, intestines, and urinary bladder). Clearance of ^3H -cytochalasin B from the blood was extremely rapid with less than 1% of the injected dose

in circulation by 15 minutes. Only liver, skeletal muscle and intestines showed significant retention of ^3H activity. All tissues had clearance of ^3H activity to below 1.5% injected dose per gram of tissue by 16 hours. Cytochalasin B Metabolism. ^3H -cytochalasin B at a dose of 1.5 or 8 $\mu\text{g/ml}$ was mixed with viable or non-viable human liver slices and media, and the amount of ^3H -cytochalasin B in media or tissue assessed by HPLC (Tables 8 and 9).

[0295] The cytotoxicity of ^3H -cytochalasin B and its subsequent metabolites was also assessed by evaluating dose dependent changes in mitochondrial function by monitoring 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) activity following a 24 hour exposure of human liver slices to the test agent (Table 10).

TABLE 10 (continued)

MTT Absorbance in Human Liver Slices Exposed to ³ H-cytochalasin B for 24 hours.	
Dose Level (µg/ml)	MTT Absorbance
8.0	0.850 +/- 0.082
^a MTT absorbance values reflect the mitochondrial viability in which high absorbance values represent viable mitochondria and while low absorbance values reflect nonfunctional mitochondria. Each value represents the mean +/- standard deviation optical density of triplicate liver samples.	

[0296] The results in Tables 8-9 indicated that 98% of the ³H-cytochalasin B was metabolized within 24 hours of administration with greater than 80% of the total reactivity being present in the media and less than 20% in the tissue. The results in Table 10 indicated that ³H-cytochalasin B or its subsequent metabolites was not cytotoxic.

[0297] To determine the metabolism of ³H-cytochalasin B in human blood, ³H-cytochalasin B (8 µg/ml) was dissolved in saline; 1:1 dilution of saline and human plasma; or 1:1 dilution of saline and human whole blood. The mixtures were incubated for 20 hours at 37 °C and then analyzed by HPLC for stability and metabolism. ³H-cytochalasin B was not metabolized when mixed with either saline or plasma. However, ³H-cytochalasin B was metabolized by human whole blood with the metabolite having an HPLC retention time and profile consistent with that seen in the human liver slice assay (see above).

Toxicity Studies. To determine the toxicity of cytochalasin B, rats (4 male and 4 female) were injected with 10 µg/ml cytochalasin B four times a day for 7 days (Table 11). Data regarding body weight changes, food consumption, food efficiency, hematology parameters, coagulation parameters, serum chemistry parameters, and gross necropsy findings were collected. The only parameter which suggested an adverse effect of cytochalasin B administration was an elevation of the mean relative heart weight in treated female animals. There were no gross or microscopic changes detected in the heart to account for the elevation. Thus, daily administration of cytochalasin B to rats at a dose of 800 µg/kg (for a total injected dose of 5600 µg/kg) may have an effect on heart weight of female (but not male) rats. However, clotted blood was not routinely removed from the heart lumens prior to weighing the heart.

TABLE 11

Group Number	Number of Animals		Treatment	Dose Level (µg/mL)	Route	Dosing Frequency	Dosing Duration
	Males	Females					
1	4	4	Biostent Control	0	IV	4 times/day (2 hrs apart)	7 days
2	4	4	Cytochalasin B	10	IV	4 times/day (2 hrs apart)	7 days

[0298] To determine the toxicity of chronic cytochalasin B administration, cytochalasin B was administered intravenously to Sprague-Dawley rats for seven days (Table 12). Data regarding food consumption, body weights, hematology parameters, clinical chemistry parameters, coagulation profiles, organ weights, clinical observations, gross necropsy findings and histopathology were collected. It was found that chronic intravenous administration of cytochalasin B at doses up to 600 µg/kg/day did not result in any indication of adverse effects or toxicity.

TABLE 12

Group Number	Number of Animals		Treatment	Dose Level (µg/mL)	Route	Dosing Frequency	Dosing Duration
	Males	Females					
1*	15	15	Control	0	Intravenous injection	4 times/day (≈2 hrs apart)	7 days
2	10	10	Cytochalasin B	1.3			7 days
3	10	10		3.9			7 days
4*	15	15		7.5			7 days
5*	15	15		7.5			7 days

* Five animals/sex/group were used for a 14-day nontreatment recovery period and were euthanized on day 22

** Five animals/sex were euthanized on days 8, 15, and 22

[0299] A similar study in dogs (Table 13), which collected data on food consumption, body weights, hematology parameters, clinical chemistry parameters, coagulation profiles, organ weights, clinical observations, thoracic cavity auscultation, ophthalmic examination, urinalysis, gross necropsy findings, and histopathology (high dose group), found that intravenous administration of cytochalasin B for seven consecutive days to beagle dogs at doses up to 648 µg/kg/day (a cumulative dose of 4,536 µg/kg) did not result in any indication of adverse effects or toxicity.

TABLE 13

Group Number	Number of Animals		Treatment	Dose Level (µg/ML)	Dose Volume (mL/kg); Flow Rate (mL/min)	Route	Dosing Frequency	Dosing Duration

* Two dogs/sex/group were held for a 14-day nontreatment recovery period and were euthanized on day 23

** Three dogs/sex were euthanized on days 9 and 23.

EXAMPLE 16

Biological Stenting of Balloon Traumatized Pig Arteries

[0300] Pig femoral arteries were traumatized as described in Example 7, and then treated with cytochalasin B. About 1.5 to about 2 ml of cytochalasin B at 0.1 $\mu\text{g/ml}$ was infused into portions of the artery that had been separated from other portions by ligatures. The artery was then pressurized for 3 minutes and the fluid aspirated. Approximately 8 to about 30 λ of the solution is retained in the interstitial space surrounding the cells in the tunica media. Ten femoral arteries (two arteries obtained from each of the 5 pigs that were treated according to the single dose protocol described in Example 7) were then evaluated histologically at 4 days or 3 weeks after cytochalasin B administration. The maximal luminal area of each artery was measured and calculated from digitized microscopic images by a BQ System IV computerized morphometric analysis system (R & M Biometrics, Inc., Nashville, TN). This experiment was repeated with 5 additional pigs (two arteries per pig; cytochalasin B dose = 0.1 $\mu\text{g/ml}$, applied for 3 minutes at 1 atm pressure; same time points). The data obtained from the two experiments were combined. Balloon traumatized pig arteries that had been treated with cytochalasin B displayed a larger luminal area at the 4 day and 3 week post-treatment time points, as compared to arteries treated with other test agents or controls.

[0301] The luminal area of the traumatized and cytochalasin B-treated segments of the arteries were also compared to the luminal area of the normal, untreated region of the femoral artery proximal to the test area. The results showed that the lumen area in the test region was approximately two times as large as the area of the normal control segment of the same artery. The negative control agents, PBS and monoclonal antibody NR-AN-01, showed no increase or a slight decrease in lumen area as compared to the normal control segment of the same artery.

[0302] A cytochalasin B dose response study was then conducted on 10 pigs, following the experimental protocol described in Example 7. Briefly, both femoral arteries in each of 2 pigs were treated with one of the following doses of cytochalasin B: 0.0 $\mu\text{g/ml}$ (i.e., PBS negative control); 0.01 $\mu\text{g/ml}$; 0.10 $\mu\text{g/ml}$; 1.0 $\mu\text{g/ml}$; and 10.0 $\mu\text{g/ml}$ as described above. The agent was delivered by intraluminal catheter at 1 atm pressure for 3 minutes, and the arteries were evaluated 3 weeks later by the morphometric analysis system described above. The ratio of treated artery luminal area to proximal normal artery luminal area was determined as a percent change in treated vs. normal area, or the artery lumen size (diameter or cross sectional area) of treated arteries relative to traumatized but untreated arteries. A significant threshold effect was observed at doses from 0.1 $\mu\text{g/ml}$ (about a 140% increase) to 1.0 $\mu\text{g/ml}$ (FIGURE 14). The sub-threshold dose (0.01 $\mu\text{g/ml}$) and negative control (PBS) exhibited about $\pm 20\%$ change in luminal area.

[0303] Electron micrographs revealed that within one hour of balloon trauma, there was a depolymerization of the myofilaments in traumatized vessels, which are contractive organelles. The depolymerization of the myofilaments is a normal physiological response of vascular smooth muscle cells to trauma, and is the first step in their transformation from a contractile to a secretory and migratory cell. Treatment of traumatized swine arteries with about 0.1 to about 10.0 $\mu\text{g/ml}$ of cytochalasin B did not result in an increased rate, or more extensive depolymerization, of the myofibrils. However, electron micrographs showed that the myofilament reformation was retarded. Based on the sustained increase in vessel diameter, the return to normal vascular contractility may be slowed more extensively than is suggested by the retarded return to normal morphology.

[0304] The traumatized and treated areas of the artery did not undergo the constriction or chronic geometrical (vascular) remodeling that normally occurred in sham controls in the pig, and which has been described in man, following PTCA. Cross sections of the artery showed a larger cross-sectional area of the total vessel, obtained by measuring the ratio of the vessel area inside the external elastic lamina (EEL) of the treated area to the mean of the total vessel area of the proximal and distal regions of the same artery, compared to arteries traumatized but not treated with cytochalasin B. In arteries that were traumatized with a torquable balloon that damages the vessel wall without tearing the tunica media, there was a more uniform intimal proliferation and the larger vessel size (area inside the EEL) resulted in a larger luminal cross-sectional area and a significant decrease in restenosis. When the vessels were extensively damaged and the tunica media was torn into, there was extensive proliferation and thrombus remodeling that resulted in highly variable intimal proliferation.

[0305] Thus, the administration of cytochalasin B to swine vascular smooth muscle cells by infusion catheter following balloon dilation trauma resulted in a more extensive retention of the artery lumen size (diameter or cross-sectional area) than was produced by the dilating balloon. This effect was achieved by replacing the entire interstitial fluid volume between cells of the tunica media with the therapeutic agent.

[0306] Moreover, cytochalasin B has a wide therapeutic index which ranges from about 0.1 to 10 $\mu\text{g/ml}$, with no evidence of toxicity at 10 $\mu\text{g/ml}$. Ten $\mu\text{g/ml}$ is the maximum saturation concentration of cytochalasin B in saline. Furthermore, the effect produced by cytochalasin B administration became more apparent over the 3 to 8 weeks following the balloon trauma. These data suggest that cytochalasin B acts as a "biological stent" when delivered to traumatized arteries.

[0307] Balloon traumatized swine femoral arteries from control and treated (0.1 $\mu\text{g/ml}$ cytochalasin B) were evaluated

at 1, 4, 7, 14, or 21 days after intervention. Morphometric analysis on frozen histologic sections of artery showed that cytochalasin B treated arteries reached a state of sustained dilation which changed very little between days 7 and 21. A two way analysis of variance indicated a statistically significant difference ($p < .05$) in the artery lumen areas over three weeks between the cytochalasin B treated and diluent control groups.

[0308] A dose-response study of balloon traumatized swine coronary arteries showed that treatment with cytochalasin B at 0.1, 1.5 or 10.0 $\mu\text{g/ml}$ (Table 14, "Biostent") resulted in sustained arterial dilation of the coronary luminal area at three weeks after intervention. Moreover, cytochalasin B administration did not result in myocardial or arterial lesions attributable to the cytochalasin B as evaluated histologically. No statistically and biologically significant changes attributable to cytochalasin B were seen in clinical chemistry parameters, hematology parameters, body weights, blood pressure or electrocardiograms.

TABLE 14

SWINE CORONARY MORPHOMETRY DATA				
Group Dose ($\mu\text{g/ml}$)*	Days Post Surgery	Mean % Lumen Area	Std Dev	P-value Unpaired T-test
Saline	4	96.5	15.2	-
0.1 $\mu\text{g/ml}$ Biostent	4	97.0	17.1	0.48
1.5 $\mu\text{g/ml}$ Biostent	4	101.7	6.8	0.28
10 $\mu\text{g/ml}$ Biostent	4	103.9	14.1	0.25
Saline	21	78.7	19.1	-
0.1 $\mu\text{g/ml}$ Biostent	21	98.0	15.5	0.004
1.5 $\mu\text{g/ml}$ Biostent	21	100.9	18.5	0.002
10 $\mu\text{g/ml}$ Biostent	21	110.9	19.2	0.004

* Dose is based on the concentration of cytochalasin B ($\mu\text{g/ml}$) in the about 8 to about 30 lambda volume of fluid delivered to about 10 to about 20% of the tunica media.

[0309] Swine coronary arteries were also traumatized by embolectomy or over-sized PTCA balloon, and then 8-16 ml of cytochalasin B at 8.0 $\mu\text{g/ml}$ was infused into the arterial wall with a MIC catheter to achieve a therapeutic dose. Controls included a diluent control and a traumatized untreated control, and all animals were sacrificed 4 weeks after intervention and coronary arteries were fixed by perfusion.

Morphometry was performed on selected sections from proximal, treated and distal segments of coronary arteries (Table 15).

TABLE 15

Swine Coronary Artery Study						
Group	Neointimal Area		Luminal Area		Arterial Area	
	Area	std	Area	std	Area	std
Untreated Control	1.88	1.62	0.77	0.38	2.19	1.07
Saline Treated Control	1.39	1.13	0.73	0.37	1.88	0.96
8.0 $\mu\text{g/ml}$ Cytochalasin B	1.56	1.24	0.58	0.30	1.80	0.70

[0310] While the data shown in Table 15, in contrast to previous studies, showed that the local delivery of cytochalasin B did not result in a statistically significant increase in luminal area, the data does show that there was a trend toward beneficial arterial remodeling as evidenced by larger arterial area bounded by the external elastic lamina in the cytochalasin B treated arteries when compared to either of the controls. The diameter of, or the area within, the EEL of the artery can be compared to controls as an indicator of the degree of vascular remodeling. The lack of a statistically significant increase in luminal area may be due to increased sample variability, increased neointimal formation, and/or increased degree of trauma.

[0311] In summary, these studies demonstrate that the administration of a cytoskeletal inhibitor, such as cytochalasin B, in an amount which can biologically stunt a traumatized vessel may also be efficacious to inhibit or reduce the proliferation of vascular smooth muscle cells.

EXAMPLE 17

Sustained Release Formulations of Cytochalasin B and Taxol

[0312] To determine the efficacy of the local, sustained release dosage forms of cytochalasin B or taxol to inhibit restenosis, cytochalasin B or taxol in a supporting structure, e.g., a "wrap," was applied to the adventitial tissue surrounding a balloon traumatized rabbit carotid artery (Groups 1-11) or a balloon traumatized pig femoral artery (Group 12) (Table 16).

[0313] The arteries in the animals in Group 1a and 1b were treated with 20 mg of cytochalasin B in 1 g of a bovine collagen gel (BioCore, Inc., Topeka, KS) that was supported by, or enclosed in, a bovine collagen mesh wrap (Skin Temp-Biosynthetic Skin Dressing, BioCore, Inc., Topeka, KS). At 1 week post treatment, the cytochalasin B treated artery in animal 1233 showed no intimal or adventitial proliferation. There was marked cell death in the outer zone of the tunica media with heterophils infiltrating the tunica media. Heterophils were present outside the wrap, but cytochalasin B inhibited heterophils and macrophages from infiltrating the wrap. The artery of the control (1249) animal had moderate intimal proliferation, and heterophils and histiocytes were infiltrating into the wrap. Cell death in the tunica media was minimal.

[0314] At 2 weeks post-treatment, there was minimal intimal and adventitial proliferation in the cytochalasin B wrap-treated area of the artery (animal 1224). The intima was loosely arranged and there was minimal heterophil infiltration. Syncytial giant cells were present. In the artery of the control wrap animal (animal 1222), there was moderate intimal proliferation with heterophils and macrophage in the wrap area. These cells were visible in the tunica media.

[0315] At three weeks post-treatment, there was no intimal proliferation observed in the cytochalasin B wrap-treated area of the artery (1244). Heterophils and syncytial giant cells were present around the wrap. There was significant necrosis of the cells in the tunica media with infiltrating heterophils and macrophages. No endothelium was present. In the control (animal 1232) artery, there was marked intimal proliferation, with well organized adventitia and perivascular tissue. Heterophils and macrophages were infiltrating the wrap. The cells in the tunica media were viable and there was a mural thrombus in the vessel lumen. Thus, inhibition of intimal proliferation was seen in the arteries of Group 1a and 1b animals treated with cytochalasin B, however, there was significant reaction to the wrap material.

[0316] The arteries in the animals in Group 2a and 2b were treated with cytochalasin B (30% wt/wt; 300 mg cytochalasin B/g silicone) in a silicone wrap (Q-7 4840, Dow Coming, Midland, MI). One week post-trauma there was no significant intimal or adventitial proliferation of smooth muscle cells (SMCs) or mesenchymal tissue (animal 1229). There was significant necrosis of the SMCs in the outer zone of the tunica media. In areas that appeared to have been minimally traumatized by the torquable balloon there was minimal to no cellular necrosis. This indicated that traumatized cells were more prone to die when exposed to this dose of cytochalasin B but that this dose was not cytotoxic to minimally traumatized or normal SMCs. There was minimal mononuclear and polymorphonuclear cell infiltration into the tunica media. A few heterophils were seen infiltrating from the vessel lumen.

[0317] In the control animal (1228), there was less cellular necrosis in the tunica media, and the necrosis present was located in the inner zone rather than the outer zone of the artery wall. Thus, cytochalasin B inhibition of cellular repair appears to increase tunica media necrosis. The control also lacked tunica media or adventitial proliferation and organization of the perivascular clot. Cellular infiltration in any area was minimal.

[0318] Two weeks after initiating cytochalasin B treatment there was complete inhibition of intimal proliferation and only minimal perivascular clot organization which was primarily due to fibrin formation and not mesenchymal proliferation (animal 1227). There was mild infiltration of polymorphonuclear cells and minimal infiltration of mononuclear cells into the tunica media and adventitia. No endothelium was present in the wrap area, except for a few small isolated foci. The control artery (animal 1226) had moderate intimal proliferation and adventitial proliferation with mesenchymal organization of the perivascular clot area. Foci of endothelial proliferation were larger and more extensive in the control animal compared to the cytochalasin B treated vessel.

[0319] With 3 weeks exposure (animal 1212) to cytochalasin B in a silicone wrap, the vessel showed marked cell loss in the tunica media which was most severe in the outer zone. Cellular infiltration in the tunica media and adventitia was minimal and endothelialization was only present in a few focal areas. There was moderate, irregular intimal proliferation; however, the intimal cells and what few endothelial cells that were present were unorganized and lack polarity. The inhibition of migration by cytochalasin B resulted in this loss of organization or polarity. The intimal proliferation was also mild in the control vessel (1230); however, the intima was well organized and was almost completely endothelialized. There was minimal cell loss from the tunica media. Thus, significant intimal inhibition was seen in the first two weeks in Group 2 treated animals.

[0320] The vessels in the animals in Group 3a and 3b were treated with 8 mg cytochalasin B in 100 mg of a pluronic gel (F-127, BASF) that was supported by a 1 cm x 1 cm bovine collagen mesh wrap. One week after treatment, the cytochalasin B treated artery of animal 1250 had mild intimal proliferation that was irregular in thickness. There was approximately 30% re-endothelialization and the tunica media cells were viable with the most significant loss (mild) being

in the inner zone of the tunica media. There was a marked pyogranulomatous reaction to the pluronic gel in the perivascular and adventitial region. Complete thrombosis of the control artery from animal 1261 prevented its evaluation.

[0321] At two weeks, the pluronic gel with cytochalasin B stimulated a marked pyogranulomatous reaction in the adventitial and perivascular tissue. There was mild, irregular intimal proliferation and complete endothelialization. The tunica media cells were viable. There appeared to be a mild cell loss from the inner zone of the tunica media. The artery of the control animal (1247) had mild, irregular intimal proliferation, complete endothelialization with plump endothelial cells and viable cells in the tunica media. There was marked pyogranulomatous inflammatory reaction to remnants of the pluronic gel.

[0322] At three weeks, the arteries of animals 1248 and 1246 showed remnants of the collagen wrap; however, the wrap was less resolved in the cytochalasin B treated animal (1248) than in the control (1246). This retardation of wrap resorption may result from cytochalasin B inhibition of macrophage migration and function. Both the treated and control had a moderate amount of intimal hyperplasia at 3 weeks, so there was no significant amount of intimal inhibition by cytochalasin B when administered in the pluronic gel. Foci of dystrophic mineralization were seen in the cytochalasin B treated artery. Thus, no inhibitory effect on the intima was observed in these animals (Group 3) at 1, 2 or 3 weeks after the initiation of treatment.

[0323] The arteries of the animals in Group 4a and b that were treated with 100 mg cytochalasin B (10% wt/wt) in a 1 g silicone wrap had significant inhibition of intimal proliferation at all time points. In the cytochalasin B wrap-treated artery of animal 1259, there was no intimal proliferation or adventitial fibrosis present at one week after treatment. Ectatic vessels were present in the adventitia and the perivascular clot was unorganized and composed of only fibrin. There was marked cell loss from the tunica media, especially in the outer zone. Heterophils were seen infiltrating the tunica media. In the control artery (1206), there was no intimal proliferation at 1 week; however, there was early fibrous organization of the perivascular clot. Cellular loss from the tunica media was more diffuse than in the cytochalasin B wrap which was most severe in the outer zone.

[0324] The cytochalasin B wrap-treated artery of animal 1253 had minimal intimal proliferation at two weeks, compared to the control (1258) wrap-treated artery which had maximal intimal proliferation. The intimal proliferation in the cytochalasin B wrap-treated artery was irregular and appeared to be the result of organizing mural thrombi by infiltrating SMC. There was only loose thin layers of platelets in the cytochalasin B wrap-treated artery, with margination of heterophils. There was no endothelialization in the cytochalasin B wrap-treated artery and <20% endothelialization in the control artery. The perivascular clot was unorganized and remained fibinous in the cytochalasin B wrap-treated artery and well organized in the control artery. The control artery had minimal cell loss from the tunica media while the cytochalasin B wrap-treated artery had marked cell loss.

[0325] At three weeks, the cytochalasin B wrap-treated artery (1251) showed minimal to no intimal proliferation. The intimal proliferation appeared to occur where there was less cell loss from the tunica media. There was early re-endothelialization in the cytochalasin B wrap-treated artery, but the cells were often rounded, loosely attached and only a few scattered foci were present (<10%). The perivascular clot in the cytochalasin B wrap-treated artery was unorganized and still consisted of fibrin, whereas the control artery was well organized with fibroblasts and collagen matrix. The control artery was completely thrombosed, there was marked intimal production in distal areas of the thrombus which were less completely organized.

[0326] The arteries in the animals in Group 5a and b were treated with 50 mg taxol in 1 g of a silicone wrap (5% wt/wt). This treatment showed marked inhibition of intimal proliferation at all time points. The taxol wrap-treated artery (animal 1278 at 1 week) had no intimal or adventitial proliferation and the perivascular clot was fibrinous and unorganized. There was a marked loss of tunica media cells and no endothelial lining present. The control (1279) had mild intimal proliferation with very early fibrosis of the fibrinous perivascular clot. The lumen was approximately 85% re-endothelialized. Both the treated and control arteries had mild heterophil infiltration into the tunica media and adventitia.

[0327] The artery from animal 1281, which had been treated for at two weeks with taxol, had no intimal proliferation, minimal adventitial fibrosis and marked cell necrosis in the tunica media with mild heterophil infiltration. Focal areas of necrosis and dystrophic mineralization were present in the adventitia and perivascular clot tissue. The artery from the control animal (1280) had moderate intimal proliferation, with marked organization of the adventitia and perivascular clot. The lumen was 100% re-endothelialized and the tunica media SMCs were viable in the control artery.

[0328] At three weeks, the taxol wrap-treated artery (1242) had no intimal proliferation and was 50% re-endothelialized with plump appearing endothelial cells. There was minimal organization of the perivascular clot and marked cell loss from the tunica media. There was mild infiltration of heterophils into the tunica media and marginating on the vessel luminal surface. The control artery (1234) had marked intimal proliferation and fibrosis of the adventitia and perivascular clot. Cells in the tunica were viable.

[0329] In Group 6a and 6b, taxol-treated arteries also had a marked inhibition 2 weeks after the wrap was removed. Animal 1276 had a taxol wrap for 2 weeks, then the wrap was removed and the animal sacrificed 3 weeks later. Following the 3 week recovery period from the taxol wrap removal (1276) there was only minimal intimal proliferation, except in a few focal areas that appeared to be thickened due to SMC organization of mural thrombi, in this artery. The adventitia

was well organized and there was a significant cell loss in the tunica media but the cells present were viable. The lumen was approximately 90% re-endothelized. The control (1277) artery had marked intimal proliferation, well organized perivascular and adventitial tissue and was 100% re-endothelized.

[0330] The results observed for Group 7a animals demonstrated that cytochalasin B-treated arteries (10% wt/wt) showed no intimal proliferation for 2 weeks. The decrease in the release rate of the cytochalasin B, however, resulted in a mild intimal proliferation by week three after wrap placement. At one week (1257), the arteries showed no intimal proliferation, and a marked necrosis of tunical media SMCs with moderate heterophil infiltration. There was no endothelium and heterophils and macrophages were margined along the lumen surface. Moreover, there was no evidence of platelet aggregates adhering to vessel wall. At two weeks (1265), the arteries were similar morphologically to the one week arteries. By three weeks (1266), the arteries showed mild irregular intimal proliferation. Furthermore, heterophils were rare in the tunica media, the lumen was 70% re-endothelized and there was early fibrosis in the adventitia with unorganized perivascular clot still present, in the treated arteries. This indicated that by 3 weeks the level of therapeutic agent had fallen below therapeutic level within the artery wall; however, there was still enough drug to have an inhibitory effect on clot organization immediately adjacent to the wrap.

[0331] The arteries of Group 8a animals, which were treated with 10% cytochalasin B for 2 weeks, then the wrap was removed and vessels evaluated 2 weeks later, had variable intimal proliferation within and between animals. The artery of animal 1254 had variable intimal proliferation which ranged from none to mild, well developed adventitial fibrosis, marked cell loss in the tunica media and focal areas of dystrophic mineralization in the outer tunica media and adventitia. The mild intimal proliferation areas were at the ends of the wrap area, suggesting an infiltration from the adjacent untreated artery regions. The lumen was approximately 60% re-endothelized. The artery of animal 1255 had mild to moderate intimal proliferation, viable cells in the tunica media and well organized tissue in the adventitia. The lumen was 100% re-endothelized. The artery in animal 1256 was completely thrombosed. Proximal to the chronic thrombus in the area of the wrap was an acute thrombus and there was moderate intimal proliferation.

[0332] While there was moderate intimal proliferation in the arteries of some animals, the proliferation in these arteries was still less than the controls in Group 9b. The mannitol control silicone wraps were on the artery for two weeks following balloon trauma and then removed and the animal necropsied and the artery histologically evaluated 1 week following wrap removal. Two of the arteries (1267 and 1268) had moderate intimal proliferation with 100% re-endothelization and one had maximum proliferation. The one with maximum intimal proliferation had an acute occluding thrombus present.

[0333] The arteries in the animals in Groups 10 and 11 were treated with 10 mg cytochalasin B loaded in 1 g of a silicone wrap (1% wt/wt) that was applied to the artery for 2 weeks, surgically removed, and histologically evaluated 2 or 4 weeks later, respectively. No significant difference was seen by qualitative evaluation between the test and control animals. Animals 1304 and 1305 had a cytochalasin B (1%) wrap for 2 weeks which was then removed. Two weeks after the removal the animal was sacrificed. The artery from animal 1304 showed moderate intimal proliferation in most areas of the wrap, in areas of marked tunica media cell necrosis and wall dystrophic mineralization the proliferation was mild. There was 100% re-endothelization and no heterophils were present in the intima or tunica media. The adventitia and perivascular clot area was well organized. The artery from animal 1305 was similar to the artery from animal 1304 morphologically. The artery from animal 1306 showed marked intimal proliferation, no infiltrating heterophils in the intima or tunica media and was 100% re-endothelized.

[0334] Animals 1307, 1308 and 1309 were exposed to a cytochalasin B (1%) wrap for 2 weeks which was then removed. Four weeks after removal the animals were sacrificed. The artery from animal 1307 had moderate intimal proliferation with focal areas of thickening due to mural thrombus organization by SMCs. There was significant loss of cells from the tunica media and the elastic lamina appear collapsed. A few heterophils were present in the adventitia. There were areas or sections in the wrap area with minimal intimal proliferation. The artery from animal 1308 showed moderate intimal proliferation with areas of marked cell loss in the tunica media and dystrophic mineralization in the outer zone of the tunica media. The vessel was 100% re-endothelized. The artery from animal 1309 had marked intimal proliferation with a well organized adventitia and perivascular region. Animal 1311 was not evaluated due to thrombosis. The results of the artery from animal 1312 were quite variable, with sections showing a range of intimal proliferation, from mild to moderate. Endothelization appeared to be complete in these arteries.

[0335] The arteries from Group 12 animals (pig femoral arteries) that were treated with 30% wt/wt cytochalasin B loaded silicone wraps showed significantly inhibited intimal proliferation for the first two weeks. While there was intimal proliferation in the arteries 3 weeks later, the proliferation was still less than the proliferation observed for the controls.

[0336] In summary, intimal proliferation of traumatized pig arteries was significantly inhibited with both cytochalasin B and taxol in sustained release dosage form. The best controlled sustained release of therapeutic agent, without the stimulation of secondary inflammatory reaction, was obtained with an adventitial wrap material comprising silicone. The silicone wraps inhibited intimal proliferation with 30% and 10% loadings of cytochalasin B; however, as the level of release drops off between 2 and 3 weeks there was initiation of intimal proliferation. When wraps were left in place for 2 weeks then surgically removed and the arteries examined from 1 to 4 weeks later, there appeared to be an intimal

proliferation rebound effect. The rebound effect occurred when the intimal proliferation of the artery treated with the therapeutic agent approaches, but is still less than, the intimal proliferation in the control artery. The animal treated with taxol appeared to have less of a rebound effect than the cytochalasin B treated arteries.

EXAMPLE 18

Delivery of Crystalline Cytochalasin B or Taxol

[0337] The *in vivo* tissue distribution of cytochalasin B administered in crystalline form was evaluated in balloon traumatized swine femoral arteries after local delivery. A femoral artery of a Yorkshire crossbred swine was balloon traumatized by overinflation and rotation of a Vascul-Flo™ Silicone embolectomy catheter. Balloon trauma was immediately followed by intravascular delivery of 10 µg/ml ³H-cytochalasin B crystals (Sigma Chemical Co., St. Louis, MO) in saline (saturated) for three minutes under 1 atm of pressure. Blood flow was resumed in the artery for five minutes prior to sacrifice of the animal. An analysis of the tissue distribution of ³H-cytochalasin B showed that this method was effective at delivering 31 µg of ³H-cytochalasin B which localized predominantly to the adventitia. ³H-cytochalasin B was visualized histologically by the presence of silver grains in an autoradiographic emulsion. Thus, these results showed that crystalline cytochalasin B can be delivered locally to a vessel wall *in vivo*.

[0338] Another study employed twenty, male, Sprague-Dawley rats. The rats underwent balloon trauma to their left carotid artery, followed by inter-arterial infusion of a solution containing 1 mg crystalline cytochalasin B in 300 µl vehicle (Hanks sterile salt solution with 0.5% Cremophor) or a diluent (saline) control. Animals were sacrificed immediately after infusion, and 2, 4, 7 and 14 days post-trauma and infusion. Post-sacrifice, the left and the right (control) carotid arteries were removed. Samples of arteries were obtained for quantitation of ³H-cytochalasin B by oxidation and scintillation counting, histopathology, autoradiography and vascular morphometry. Histopathology documented uniform, circumferential balloon trauma in the arterial wall of the left carotid arteries.

[0339] Autoradiographically, cytochalasin B crystals were present on day 0 in intraluminal fibrin clots, adherent to the intima but rarely present in the adventitia. By day 2, the number of crystals diminished compared to day 0, and by day 4 crystals were not detectable by autoradiography. The autoradiographic results correlated closely with quantitative assessment of ³H-cytochalasin B by oxidation and scintillation counts in which approximately 8 µg of cytochalasin B was present over the treated length of artery on day 0 and slightly less than 2 ng was present by day 2. However, one of the two animals sacrificed on day 4 still had cytochalasin B levels above background. Morphometric analysis of left carotid arteries of crystalline cytochalasin B treated rats compared to diluent treated rats showed no statistically significant reduction in neointima formation. However, the five treated rats had a higher mean luminal area and a smaller neointimal area than diluent treated control.

[0340] Cytochalasin B and taxol were administered periadventitially. Three groups of seven adult male rats underwent balloon trauma of the left carotid artery immediately followed by periadventitial placement of either cytochalasin B crystals (7.8 - 11.8 mg/rat), taxol crystals (3.4 - 6.5 mg/rat), or no drug (control). The cytochalasin B and taxol crystals were placed in a uniform pattern which covered the surgically exposed surface of the carotid artery, followed by closure of surrounding subcutaneous skin and tissues by sutures. Fourteen days later rats were sacrificed and their carotid arteries processed for histologic and morphometric analysis.

[0341] Two cytochalasin B treated animals died due to acute hemorrhage at the surgical site and hypovolemic shock prior to the 14 day sacrifice point. Two additional cytochalasin B treated and one taxol treated animal were sacrificed with rapidly enlarging subcutaneous swelling and hemorrhage at the surgical site prior to the 14 day sacrifice point. All animals treated with either cytochalasin B or taxol crystals had significant toxicity at the surgical site which was characterized by varying degrees of hemorrhage, necrosis of the vessel wall, necrosis of adjacent skeletal muscle and inflammation. In addition, both the taxol and cytochalasin B treated animals had a delay in post-surgical weight gain.

[0342] The three cytochalasin B treated, 6 taxol treated and 7 control animals which survived to the 14 day sacrifice point were evaluated morphometrically. Taxol treated animals had statistically significantly larger luminal areas and no neointimal proliferation when compared to the balloon traumatized, untreated control animals in a two-tailed t-test with $p < 0.05$. Cytochalasin B treated animals showed no statistical difference from the controls in luminal area, neointimal area, medial area, areas bounded by the internal and external elastic lamina or intimal to medial ratio.

[0343] To further evaluate the efficacy of crystalline taxol to inhibit neointimal formation in rats, four groups of 5-6 adult male rats underwent balloon trauma of the left carotid artery followed immediately by periadventitial delivery of 1, 0.1, 0.01 or 0 mg of taxol crystals in 500 µg of a pluronic polymer in gel matrix. Fourteen days later, the rats were sacrificed, serum was collected and their carotid arteries were processed for histologic and morphometric analysis.

[0344] Five animals (3 - 1 mg and 2 - 0.01 mg) died post-surgically due to technical difficulties. Grossly, myonecrosis of the adjacent skeletal muscle (pale white regions of the musculature) was present in 3/3, 1/5, 0/4 and 0/5 animals in the 1 mg, 0.1 mg, 0.01 mg and control groups, respectively. Histologically, myonecrosis was confirmed in the adjacent skeletal muscle and in some regions of the tunica media of the left carotid artery in the 1 mg treatment group but not

in the other groups. Morphometrically, there was no statistical significance in luminal area, neointimal area, area bounded by the internal elastic lamina, area of the tunica media, area bounded by the external elastic lamina or neointimal/medial ratio when compared by analysis of variance using the excell data analysis software package.

[0345] Periadventitial treatment of rat carotid arteries with 1 mg taxol crystals in 500 mg of a pluronic gel resulted in gross myonecrosis of the adjacent musculature. While the number of animals surviving in this group was too low to assess for statistical significance in the reduction of neointimal formation, neointimal area was 38% less than that of control animals.

[0346] For animals treated with 0.1 and 0.01 mg taxol, a reduction in their neointimal area and neointimal/medial ratio was observed when compared to control animals, although this did not reach statistical significance given the small number of animals per group. Moreover, animals in the lower dose groups showed no (0.01 mg), minimal (0.1 mg) or limited (1.0 mg) toxicity, indicating that lower doses may be efficacious and exhibit fewer adverse side effects than doses greater than 1.0 mg.

Claims

1. The use of a dosage form comprising a cytoskeletal inhibitor, wherein the cytoskeletal inhibitor is in substantially crystalline form and wherein the crystals are of a size which results in sustained release of the cytoskeletal inhibitor, for the preparation of a medicament to inhibit or reduce diminution in vessel lumen area of a procedurally traumatised mammalian blood vessel, wherein said dosage form is administered to the mammalian blood vessel.
2. The use as claimed in claim 1 wherein the cytoskeletal inhibitor comprises taxol or an analog thereof or cytochalasin or an analog thereof.
3. The use as claimed in claim 1 or 2 wherein the cytoskeletal inhibitor comprises about 5 to 40 weight percent of the dosage form.
4. The use as claimed in claim 1 or 2 wherein the cytoskeletal inhibitor comprises about 3 to 50 weight percent of the dosage form.
5. The use as claimed in any one of claims 1 to 4 wherein the cytoskeletal inhibitor is administered via an implantable device.
6. The use as claimed in claim 5 wherein the cytoskeletal inhibitor is releasably embedded in, coated on, or embedded in and coated on, the implantable device.
7. The use as claimed in any one of claims 1 to 5 wherein the crystalline form is dispersed in a liquid vehicle and is administered by a catheter.
8. A dosage form as claimed in any one of claims 1 to 7 for use as a medicament.
9. The use as claimed in any one of claims 1 to 7 wherein the administration is before or during procedural vascular trauma.
10. The use as claimed in any one of claims 1 to 7 wherein the administration is after procedural vascular trauma.
11. The use as claimed in any one of claims 1 to 7 wherein the vessel is traumatized by angioplasty, placement of a stent, placement of a shunt, or natural grafting, or any combination thereof.
12. The use of a dosage form comprising a cytochalasin or an analog thereof in solid form in a non-liquid matrix for the preparation of a medicament to inhibit or reduce diminution in vessel lumen area of a mammalian blood vessel wherein said dosage form is administered to the mammalian blood vessel wherein the non-liquid matrix is a gel, paste or membrane.
13. The use of claim 12 wherein the cytochalasin or analog thereof is 5 to 70 weight percent of the dosage form.
14. The use as claimed in claim 12 wherein the dosage form comprises an analog of cytochalasin.

15. The use as claimed in claim 12 wherein the dosage form comprises crystals or microcrystals of the cytochalasin or analog thereof.
- 5 16. The use as claimed in any one of claims 1 to 15 wherein the cytochalasin or analog thereof is administered via an implantable device.
17. The use as claimed in claim 16 wherein the cytochalasin or analog thereof is releasably embedded in, coated on, or embedded in and coated on, the implantable device, the matrix, or both.
- 10 18. The use as claimed in claim 6 or 17 wherein the device is an adventitial wrap, an artificial graft, a stent or a shunt.
19. A kit comprising an implantable device adapted for the delivery of at least one cytoskeletal inhibitor to a site in the lumen of a traumatized mammalian vessel and a unit dosage form comprising a dosage form as defined in any one of claims 1 to 7.
- 15 20. The kit of claim 19 wherein the device is a catheter.
21. A pharmaceutical composition suitable for delivery via an implantable device, comprising:
- 20 (a) an amount of a cytochalasin or an analog thereof in solid form effective to inhibit or reduce stenosis or restenosis of a mammalian blood vessel traumatized by a surgical procedure; and
(b) a pharmaceutically acceptable non-liquid release matrix for said cytochalasin wherein the non-liquid release matrix is a gel, paste or membrane;
- 25 wherein the device is a shunt or an adventitial wrap.
22. The composition of claim 21 wherein the solid form is crystalline.
23. A pharmaceutical composition comprising an amount of a substantially pure solid cytochalasin or analog thereof effective to inhibit or reduce stenosis or restenosis of a mammalian blood vessel traumatized by a surgical procedure, wherein said cytochalasin or analog thereof is in crystalline form.
- 30 24. The pharmaceutical composition of claim 21 or 23 wherein the cytochalasin or analog thereof is 5 to 70 weight percent of the pharmaceutical composition.
- 35 25. A therapeutic shunt comprising an amount of a cytoskeletal inhibitor in solid form effective to inhibit or reduce stenosis or restenosis following placement of the therapeutic shunt.
26. A therapeutic adventitial wrap comprising an amount of a cytoskeletal inhibitor in solid form effective to inhibit or reduce stenosis or restenosis following placement of the therapeutic wrap.
- 40 27. The therapeutic shunt or adventitial wrap of claim 25 or 26 wherein the cytoskeletal inhibitor comprises a cytochalasin or an analog thereof or taxol or an analog thereof.
- 45 28. The therapeutic shunt or adventitial wrap of claim 25 or 26 wherein the solid form is crystalline.
29. The therapeutic shunt or adventitial wrap of claim 25 or 26 wherein the cytoskeletal inhibitor comprises about 5 to 70 weight percent of the dosage form.
- 50 30. A therapeutic device comprising a stent overlaid with an artificial graft, wherein the artificial graft comprises about 5 to 70 weight percent of a cytoskeletal inhibitor in solid form.
31. The therapeutic shunt or adventitial wrap of claim 29 wherein the cytoskeletal inhibitor comprises 10 to 30 weight percent of the dosage form.
- 55 32. The therapeutic shunt or adventitial wrap of claim 29 wherein the cytoskeletal inhibitor comprises 30 to 50 weight percent of the dosage form.

33. The therapeutic device of claim 30 wherein the cytoskeletal inhibitor comprises 10 to 30 weight percent.

34. The therapeutic device of claim 30 wherein the cytoskeletal inhibitor comprises 30 to 50 weight percentage.

5

Patentansprüche

1. Verwendung einer Dosierungsform, umfassend einen Cytoskelettinhibitor, worin der Cytoskelettinhibitor in im Wesentlichen kristalliner Form vorliegt und worin die Kristalle eine Größe aufweisen, die zu einer anhaltenden Freisetzung des Cytoskelettinhibitors führt, zur Herstellung eines Medikaments zur Inhibierung oder Reduzierung der Verringerung der Gefäßlumenfläche eines durch eine Prozedur traumatisierten Säugerblutgefäßes, wobei die Dosierungsform dem Säugerblutgefäß verabreicht wird.
2. Verwendung nach Anspruch 1, wobei der Cytoskelettinhibitor Taxol oder ein Analogon davon oder Cytochalasin oder ein Analogon davon umfasst.
3. Verwendung nach Anspruch 1 oder 2, wobei der Cytoskelettinhibitor etwa 5 bis 40 Gewichtsprozent der Dosierungsform umfasst.
4. Verwendung nach Anspruch 1 oder 2, wobei der Cytoskelettinhibitor etwa 3 bis 50 Gewichtsprozent der Dosierungsform umfasst.
5. Verwendung nach einem der Ansprüche 1 bis 4, wobei der Cytoskelettinhibitor über eine implantierbare Vorrichtung verabreicht wird.
6. Verwendung nach Anspruch 5, wobei der Cytoskelettinhibitor freisetzbar in der implantierbaren Vorrichtung eingebettet ist, auf der implantierbaren Vorrichtung als Schicht aufgetragen ist, oder in der implantierbaren Vorrichtung eingebettet und darauf als Schicht aufgetragen ist.
7. Verwendung nach einem der Ansprüche 1 bis 5, wobei die kristalline Form in einem flüssigen Träger dispergiert ist und über einen Katheter verabreicht wird.
8. Dosierungsform nach einem der Ansprüche 1 bis 7 zur Verwendung als Medikament.
9. Verwendung nach einem der Ansprüche 1 bis 7, wobei die Verabreichung vor oder während des durch die Prozedur bedingten vaskulären Traumas erfolgt.
10. Verwendung nach einem der Ansprüche 1 bis 7, wobei die Verabreichung nach dem durch die Prozedur bedingten vaskulären Trauma erfolgt.
11. Verwendung nach einem der Ansprüche 1 bis 7, wobei das Gefäß durch Angioplastie, Einsetzen eines Stents, Einsetzen eines Shunts oder durch natürliche Transplantation, oder jede Kombination davon traumatisiert wird.
12. Verwendung einer Dosierungsform, umfassend ein Cytochalasin oder ein Analogon davon in fester Form in einer nicht-flüssigen Matrix zur Herstellung eines Medikaments zur Inhibierung oder Reduzierung der Verringerung der Gefäßlumenfläche eines Säugerblutgefäßes, wobei die Dosierungsform dem Säugerblutgefäß verabreicht wird, wobei die nicht-flüssige Matrix ein Gel, eine Paste oder eine Membran ist.
13. Verwendung nach Anspruch 12, wobei das Cytochalasin oder das Analogon davon 5 bis 70 Gewichtsprozent der Dosierungsform ausmacht.
14. Verwendung nach Anspruch 12, wobei die Dosierungsform ein Analogon von Cytochalasin umfasst.
15. Verwendung nach Anspruch 12, wobei die Dosierungsform Kristalle oder Mikrokristalle des Cytochalasins oder des Analogons davon umfasst.
16. Verwendung nach einem der Ansprüche 1 bis 15, wobei das Cytochalasin oder das Analogon davon über eine implantierbare Vorrichtung verabreicht wird.

17. Verwendung nach Anspruch 16, wobei das Cytochalasin oder das Analogon davon freisetzbar in der implantierbaren Vorrichtung, der Matrix, oder beiden eingebettet ist, darauf als Schicht aufgetragen ist, oder darin eingebettet und darauf als Schicht aufgetragen ist.
- 5 18. Verwendung nach Anspruch 6 oder 17, wobei die Vorrichtung eine Umhüllung der Adventitia, ein künstliches Transplantat, ein Stent oder ein Shunt ist.
- 10 19. Kit, umfassend eine implantierbare Vorrichtung, die für die Abgabe wenigstens eines Cytoskelettinhibitors an eine Stelle im Lumen eines traumatisierten Säugergefäßes angepasst ist, und eine Einheitsdosisform, die eine Dosierungsform nach einem der Ansprüche 1 bis 7 umfasst.
20. Kit nach Anspruch 19, wobei die Vorrichtung ein Katheter ist.
- 15 21. Pharmazeutische Zusammensetzung, die für die Abgabe über eine implantierbare Vorrichtung geeignet ist, wobei die Zusammensetzung umfasst:
- (a) eine Menge eines Cytochalasins oder eines Analogons davon in fester Form, welche die Stenose oder Restenose eines Säugerblutgefäßes wirksam inhibiert oder reduziert, das durch einen chirurgischen Eingriff traumatisiert ist;
- 20 (b) eine pharmazeutisch verträgliche nicht-flüssige Freisetzungsmatrix für das Cytochalasin, wobei die nicht-flüssige Freisetzungsmatrix ein Gel, eine Paste oder eine Membran ist;
- wobei die Vorrichtung ein Shunt oder eine Umhüllung der Adventitia ist.
- 25 22. Zusammensetzung nach Anspruch 21, wobei die feste Form kristallin ist.
- 30 23. Pharmazeutische Zusammensetzung, umfassend eine Menge eines im Wesentlichen reinen festen Cytochalasins oder Analogons davon, welche die Stenose oder Restenose eines durch einen chirurgischen Eingriff traumatisierten Säugerblutgefäßes wirksam inhibiert oder reduziert, wobei das Cytochalasin oder das Analogon davon in kristalliner Form vorliegt.
- 35 24. Pharmazeutische Zusammensetzung nach Anspruch 21 oder 23, wobei das Cytochalasin oder das Analogon davon 5 bis 70 Gewichtsprozent der pharmazeutischen Zusammensetzung ausmacht.
- 40 25. Therapeutischer Shunt, umfassend eine Menge eines Cytoskelettinhibitors in fester Form, welche die Stenose oder Restenose nach Einsetzen des therapeutischen Shunts wirksam inhibiert oder reduziert.
26. Therapeutische Umhüllung der Adventitia, umfassend eine Menge eines Cytoskelettinhibitors in fester Form, welche die Stenose oder Restenose nach Einsetzen der therapeutischen Umhüllung wirksam inhibiert oder reduziert.
- 45 27. Therapeutischer Shunt oder Umhüllung der Adventitia nach Anspruch 25 oder 26, wobei der Cytoskelettinhibitor ein Cytochalasin oder ein Analogon davon oder Taxol oder ein Analogon davon umfasst.
28. Therapeutischer Shunt oder Umhüllung der Adventitia nach Anspruch 25 oder 26, wobei die feste Form kristallin ist.
- 50 29. Therapeutischer Shunt oder Umhüllung der Adventitia nach Anspruch 25 oder 26, wobei der Cytoskelettinhibitor etwas 5 bis 70 Gewichtsprozent der Dosierungsform umfasst.
30. Therapeutische Vorrichtung, umfassend einen mit einem künstlichen Transplantat belegten Stent, wobei das künstliche Transplantat etwa 5 bis 70 Gewichtsprozent eines Cytoskelettinhibitors in fester Form umfasst.
- 55 31. Therapeutischer Shunt oder Umhüllung der Adventitia nach Anspruch 29, wobei der Cytoskelettinhibitor 10 bis 30 Gewichtsprozent der Dosierungsform umfasst.
32. Therapeutischer Shunt oder Umhüllung der Adventitia nach Anspruch 29, wobei der Cytoskelettinhibitor 30 bis 50 Gewichtsprozent der Dosierungsform umfasst.
33. Therapeutische Vorrichtung nach Anspruch 30, wobei der Cytoskelettinhibitor 10 bis 30 Gewichtsprozent umfasst.

34. Therapeutische Vorrichtung nach Anspruch 30, wobei der Cytoskeletthinhibitor 30 bis 50 Gewichtsprozent umfasst.

Revendications

1. Utilisation d'une formule de posologie comprenant un inhibiteur cytosquelettique, dans laquelle l'inhibiteur cytosquelettique est sous forme sensiblement cristalline et dans laquelle les cristaux sont d'une taille qui conduit à la libération prolongée de l'inhibiteur cytosquelettique, pour la préparation d'un médicament pour inhiber ou réduire la diminution de l'aire de lumière vasculaire d'un vaisseau sanguin de mammifère traumatisé de manière chirurgicale, dans laquelle ladite formule de posologie est administrée au vaisseau sanguin de mammifère.
2. Utilisation selon la revendication 1 dans laquelle l'inhibiteur cytosquelettique comprend le taxol ou un analogue de celui-ci ou la cytochalasine ou un analogue de celle-ci.
3. utilisation selon la revendication 1 ou 2 dans laquelle l'inhibiteur cytosquelettique représente d'environ 5 à 40 pour cent en poids de la formule de posologie.
4. Utilisation selon la revendication 1 ou 2 dans laquelle l'inhibiteur cytosquelettique représente d'environ 3 à 50 pour cent en poids de la formule de posologie.
5. utilisation selon l'une quelconque des revendications 1 à 4 dans laquelle l'inhibiteur cytosquelettique est administré à l'aide d'un dispositif implantable.
6. Utilisation selon la revendication 5 dans laquelle l'inhibiteur cytosquelettique est incorporé de manière libérable dans, enrobé sur, ou incorporé dans et enrobé sur, le dispositif implantable.
7. Utilisation selon l'une quelconque des revendications 1 à 5 dans laquelle la forme cristalline est dispersée dans un véhicule liquidé et est administrée par un cathéter.
8. Formule de posologie selon l'une quelconque des revendications 1 à 7 pour utilisation en tant que médicament.
9. Utilisation selon l'une quelconque des revendications 1 à 7 dans laquelle l'administration est effectuée avant ou pendant un traumatisme vasculaire chirurgical.
10. Utilisation selon l'une quelconque des revendications 1 à 7 dans laquelle l'administration est effectuée après un traumatisme vasculaire chirurgical.
11. Utilisation selon l'une quelconque des revendications 1 à 7 dans laquelle le vaisseau est traumatisé par une angioplastie, le placement d'une endoprothèse vasculaire, le placement d'une dérivation, ou une greffe naturelle ou une combinaison de ceux-ci.
12. Utilisation d'une formule de posologie comprenant une cytochalasine ou un analogue de celle-ci sous forme solide dans une matrice non liquide pour la préparation d'un médicament pour inhiber ou réduire la diminution de l'aire de la lumière d'un vaisseau d'un vaisseau sanguin de mammifère dans laquelle ladite formule de posologie est administrée au vaisseau sanguin de mammifère dans laquelle la matrice non liquide est un gel, une pâte ou une membrane.
13. Utilisation selon la revendication 12 dans laquelle la cytochalasine ou un analogue de celle-ci représente de 5 à 70 pour cent en poids de la formule de posologie.
14. Utilisation selon la revendication 12 dans laquelle la formule de posologie comprend un analogue de cytochalasine.
15. Utilisation selon la revendication 12 dans laquelle la formule de posologie comprend des cristaux ou des micro-cristaux de la cytochalasine ou un analogue de celle-ci.
16. Utilisation selon l'une quelconque des revendications 1 à 15 dans laquelle la cytochalasine ou un analogue de celle-ci est administrée à l'aide d'un dispositif implantable.

17. Utilisation selon la revendication 16 dans laquelle la cytochalasine ou un analogue de celle-ci est incorporée de manière libérale dans, enrobée sur, ou incorporée dans et enrobée sur le dispositif implantable, la matrice, ou les deux.
18. Utilisation selon la revendication 6 ou 17 dans laquelle le dispositif est une enveloppe adventitielle, une greffe artificielle, une endoprothèse vasculaire ou une dérivation.
19. Kit comprenant un dispositif implantable adapté pour la délivrance d'au moins un inhibiteur cytosquelettique à un site dans la lumière d'un vaisseau de mammifère traumatisé et une formule de posologie unitaire comprenant une formule de posologie comme définie dans l'une quelconque des revendications 1 à 7.
20. Kit selon la revendication 19 dans lequel le dispositif est un cathéter.
21. Composition pharmaceutique adaptée pour la délivrance à l'aide d'un dispositif implantable, comprenant :
- (a) une quantité d'une cytochalasine ou un analogue de celle-ci sous forme solide efficace pour inhiber ou réduire la sténose ou la resténose d'un vaisseau sanguin de mammifère traumatisé par une procédure chirurgicale ; et
 - (b) une matrice de libération non liquide pharmaceutiquement acceptable pour ladite cytochalasine dans laquelle la matrice de libération non liquide est un gel, une pâte ou une membrane ;
- dans laquelle le dispositif est une dérivation ou une enveloppe adventitielle.
22. Composition selon la revendication 21 dans laquelle la forme solide est cristalline.
23. Composition pharmaceutique comprenant une quantité d'une cytochalasine solide sensiblement pure ou un analogue de celle-ci efficace pour inhiber ou réduire la sténose ou la resténose d'un vaisseau sanguin de mammifère traumatisé par une procédure chirurgicale, dans laquelle ladite cytochalasine ou un analogue de celle-ci est sous forme cristalline.
24. Composition pharmaceutique selon la revendication 21 ou 23 dans laquelle la cytochalasine ou un analogue de celle-ci représente de 5 à 70 pour cent en poids de la composition pharmaceutique.
25. Dérivation thérapeutique comprenant une quantité d'un inhibiteur cytosquelettique sous forme solide efficace pour inhiber ou réduire la sténose ou la resténose après placement d'une dérivation thérapeutique.
26. Enveloppe adventitielle thérapeutique comprenant une quantité d'un inhibiteur cytosquelettique sous forme solide efficace pour inhiber ou réduire la sténose ou la resténose après placement de l'enveloppe thérapeutique.
27. Dérivation ou enveloppe adventitielle thérapeutique selon la revendication 25 ou 26 dans laquelle l'inhibiteur cytosquelettique comprend une cytochalasine ou un analogue de celle-ci ou le taxol ou un analogue de celui-ci.
28. Dérivation ou enveloppe adventitielle thérapeutique selon la revendication 25 ou 26 dans laquelle la forme solide est cristalline.
29. Dérivation ou enveloppe adventitielle thérapeutique selon la revendication 25 ou 26 dans laquelle l'inhibiteur cytosquelettique représente de 5 à 70 pour cent en poids de la formule de posologie.
30. Dispositif thérapeutique comprenant une endoprothèse vasculaire recouverte avec une greffe artificielle, dans lequel la greffe artificielle comprend d'environ 5 à 70 pour cent en poids d'un inhibiteur cytosquelettique sous forme solide.
31. Dérivation ou enveloppe adventitielle thérapeutique selon la revendication 29 dans laquelle l'inhibiteur cytosquelettique représente de 10 à 30 pour cent en poids de la formule de posologie.
32. Dérivation ou enveloppe adventitielle thérapeutique selon la revendication 29 dans laquelle l'inhibiteur cytosquelettique représente de 30 à 50 pour cent en poids de la formule de posologie.

33. Dispositif thérapeutique selon la revendication 30 dans laquelle l'inhibiteur cytosquelettique représente de 10 à 30 pour cent en poids.

34. Dispositif thérapeutique selon la revendication 30 dans laquelle l'inhibiteur cytosquelettique représente de 30 à 50 pour cent en poids.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☒ **BLACK BORDERS**
- ☐ **IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- ☐ **FADED TEXT OR DRAWING**
- ☐ **BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- ☐ **SKEWED/SLANTED IMAGES**
- ☐ **COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- ☒ **GRAY SCALE DOCUMENTS**
- ☐ **LINES OR MARKS ON ORIGINAL DOCUMENT**
- ☐ **REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- ☐ **OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
